

ICL8211, ICL8212

**OBSOLETE PRODUCT
NO RECOMMENDED REPLACEMENT**

October 1999

Programmable Voltage Detectors

Features

- High Accuracy Voltage Sensing and Generation
- Internal Reference 1.15V Typical
- Low Sensitivity to Supply Voltage and Temperature Variations
- Wide Supply Voltage Range Typ. 1.8V to 30V
- Essentially Constant Supply Current Over Full Supply Voltage Range
- Easy to Set Hysteresis Voltage Range
- Defined Output Current Limit ICL8211
- High Output Current Capability ICL8212

Applications

- Low Voltage Sensor/Indicator
- High Voltage Sensor/Indicator
- Nonvolatile Out-of-Voltage Range Sensor/Indicator
- Programmable Voltage Reference or Zener Diode
- Series or Shunt Power Supply Regulator
- Fixed Value Constant Current Source

Description

The Intersil ICL8211/8212 are micropower bipolar monolithic integrated circuits intended primarily for precise voltage detection and generation. These circuits consist of an accurate voltage reference, a comparator and a pair of output buffer/drivers.

Specifically, the ICL8211 provides a 7mA current limited output sink when the voltage applied to the 'THRESHOLD' terminal is less than 1.15V (the internal reference). The ICL8212 requires a voltage in excess of 1.15V to switch its output on (no current limit). Both devices have a low current output (HYSTERESIS) which is switched on for input voltages in excess of 1.15V. The HYSTERESIS output may be used to provide positive and noise free output switching using a simple feedback network.

Ordering Information

PART NUMBER	TEMPERATURE RANGE	PACKAGE

NOTES:

1. The maximum output current of the ICL8211 is limited by design to 15mA under any operating conditions. The output voltage may be sustained at any voltage up to +30V as long as the maximum power dissipation of the device is not exceeded.
2. The maximum output current of the ICL8212 is not defined. And systems using the ICL8212 must therefore ensure that the output current does not exceed 30mA and that the maximum power dissipation of the device is not exceeded.
3. Threshold Trip Voltage is 0.80V(min) to 1.30V(max). At $I_{OUT} = 3mA$.

Detailed Description

The ICL8211 and ICL8212 use standard linear bipolar integrated circuit technology with high value thin film resistors which define extremely low value currents.

Components Q_1 through Q_{10} and R_1 , R_2 and R_3 set up an accurate voltage reference of 1.15V. This reference voltage is close to the value of the bandgap voltage for silicon and is highly stable with respect to both temperature and supply voltage. The deviation from the bandgap voltage is necessary due to the negative temperature coefficient of the thin film resistors (-5000 ppm per °C).

Components Q_2 through Q_9 and R_2 make up a constant current source; Q_2 and Q_3 are identical and form a current mirror. Q_8 has 7 times the emitter area of Q_9 , and due to the current mirror, the collector currents of Q_8 and Q_9 are forced to be equal and it can be shown that the collector current in Q_8 and Q_9 is

$$I_C (Q_8 \text{ or } Q_9) = \frac{1}{R_2} \times \frac{kT}{q} \ln 7$$

or approximately $1\mu\text{A}$ at $+25^\circ\text{C}$

Where k = Boltzman's Constant

q = Charge on an Electron

and T = Absolute Temperature in °K

Transistors Q_5 , Q_6 , and Q_7 assure that the V_{CE} of Q_3 , Q_4 , and Q_9 remain constant with supply voltage variations. This ensures a constant current supply free from variations.

The base current of Q_1 provides sufficient start up current for the constant source; there being two stable states for this type of circuit - either ON as defined above, or OFF if no start up current is provided. Leakage current in the transistors is not sufficient in itself to guarantee reliable startup.

Q_4 is matched to Q_3 and Q_2 ; Q_{10} is matched to Q_9 . Thus the IC and V_{BE} of Q_{10} are identical to that of Q_9 or Q_8 . To generate the bandgap voltage, it is necessary to sum a voltage equal to the base emitter voltage of Q_9 to a voltage proportional to the difference of the base emitter voltages of two transistors Q_8 and Q_9 operating at two current densities.

$$\text{Thus } 1.5 = V_{BE} (Q_9 \text{ or } Q_{10}) + \frac{R_3}{R_2} \times \frac{kT}{q}$$

$$\text{which provides: } \frac{R_3}{R_2} = 12 \text{ (approximately.)}$$

The total supply current consumed by the voltage reference section is approximately $6\mu\text{A}$ at room temperature. A voltage at the THRESHOLD input is compared to the reference 1.15V by the comparator consisting of transistors Q_{11} through Q_{17} . The outputs from the comparator are limited to two diode drops less than $V+$ or approximately 1.1V. Thus the base current into the hysteresis output transistor is limited to about 500nA and the collector current of Q_{19} to $100\mu\text{A}$.

In the case of the ICL8211, Q_{21} is proportioned to have 70 times the emitter area of Q_{20} thereby limiting the output current to approximately 7mA , whereas for the ICL8212

ICL8211, ICL8212

almost all the collector current of Q_{19} is available for base drive to Q_{21} , resulting in a maximum available collector current of the order of 30mA. It is advisable to externally limit this current to 25mA or less.

Applications

The ICL8211 and ICL8212 are similar in many respects, especially with regard to the setup of the input trip conditions and hysteresis circuitry. The following discussion describes both devices, and where differences occur they are clearly noted.

General Information

Threshold Input Considerations

Although any voltage between -5V and V_+ may be applied to the THRESHOLD terminal, it is recommended that the THRESHOLD voltage does not exceed about +6V since above that voltage the threshold input current increases sharply. Also, prolonged operation above this voltage will lead to degradation of device characteristics.

The outputs change states with an input THRESHOLD voltage of approximately 1.15V. Input and output waveforms are shown in Figure 21 for a simple 1.15V level detector.

FIGURE 21. VOLTAGE LEVEL DETECTION

The HYSTERESIS output is a low current output and is intended primarily for input threshold voltage hysteresis applications. If this output is used for other applications it is suggested that output currents be limited to 10 μ A or less.

The regular OUTPUT's from either the ICL8211 or ICL8212 may be used to drive most of the common logic families

such as TTL or CMOS using a single pullup resistor. There is a guaranteed TTL fanout of 2 for the ICL8211 and 4 for the ICL8212.

A principal application of the ICL8211 is voltage level detection, and for that reason the OUTPUT current has been limited to typically 7mA to permit direct drive of an LED connected to the positive supply without a series current limiting resistor.

On the other hand the ICL8212 is intended for applications such as programmable zener references, and voltage regulators where output currents well in excess of 7mA are desirable. Therefore, the output of the ICL8212 is not current limited, and if the output is used to drive an LED, a series current limiting resistor must be used.

In most applications an input resistor divider network may be used to generate the 1.15V required for V_{TH} . For high accuracy, currents as large as 50 μ A may be used, however for those applications where current limiting may be desirable, (such as when operating from a battery) currents as low as 6mA may be considered without a great loss of accuracy. 6mA represents a practical minimum, since it is about this level where the device's own input current becomes a significant percentage of that flowing in the divider network.

FIGURE 22. OUTPUT LOGIC INTERFACE

FIGURE 23. INPUT RESISTOR NETWORK CONSIDERATIONS

Case 1. High accuracy required, current in resistor network unimportant Set $I = 50\mu$ A for $V_{TH} = 1.15V \therefore R_1 \rightarrow 20k\Omega$

Case 2. Good accuracy required, current in resistor network important Set $I = 7.5\mu$ A for $V_{TH} = 1.15V \therefore R_1 \rightarrow 150k\Omega$

ICL8211, ICL8212

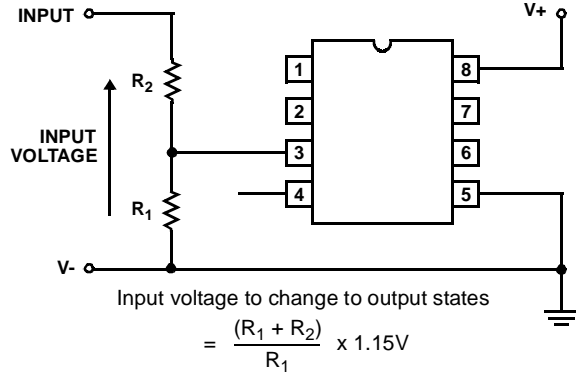

FIGURE 24. RANGE OF INPUT VOLTAGE GREATER THAN +1.15 VOLTS

Setup Procedures For Voltage Level Detection

Case 1. Simple voltage detection no hysteresis

Unless an input voltage of approximately 1.15V is to be detected, resistor networks will be used to divide or multiply the unknown voltage to be sensed. Figure 25 shows procedures on how to set up resistor networks to detect INPUT VOLTAGES of any magnitude and polarity.

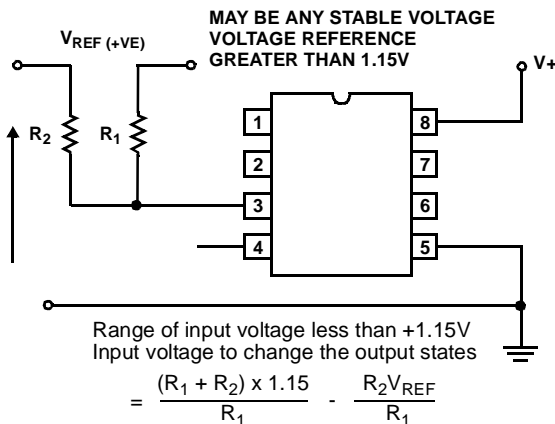

FIGURE 25. INPUT RESISTOR NETWORK SETUP PROCEDURES

For supply voltage level detection applications the input resistor network is connected across the supply terminals as shown in Figure 26.

FIGURE 26. COMBINED INPUT AND SUPPLY VOLTAGES

Case 2. Use of the HYSTERESIS function

The disadvantage of the simple detection circuits is that there is a small but finite input range where the outputs are neither totally 'ON' nor totally 'OFF'. The principle behind hysteresis is to provide positive feedback to the input trip point such that there is a voltage difference between the input voltage necessary to turn the outputs ON and OFF.

The advantage of hysteresis is especially apparent in electrically noisy environments where simple but positive voltage detection is required. Hysteresis circuitry, however, is not limited to applications requiring better noise performance but may be expanded into highly complex systems with multiple voltage level detection and memory applications—refer to specific applications section.

There are two simple methods to apply hysteresis to a circuit for use in supply voltage level detection. These are shown in Figure 27.

The circuit of Figure 27A requires that the full current flowing in the resistor network be sourced by the HYSTERESIS output, whereas for circuit Figure 27B the current to be sourced by the HYSTERESIS output will be a function of the ratio of the two trip points and their values. For low values of hysteresis, circuit Figure 27B is to be preferred due to the offset voltage of the hysteresis output transistor.

A third way to obtain hysteresis (ICL8211 only) is to connect a resistor between the OUTPUT and the THRESHOLD terminals thereby reducing the total external resistance between the THRESHOLD and GROUND when the OUTPUT is switched on.

Practical Applications

Low Voltage Battery Indicator (Figure 28)

This application is particularly suitable for portable or remote operated equipment which requires an indication of a depleted or discharged battery. The quiescent current taken by the system will be typically 35μA which will increase to 7mA when the lamp is turned on. R₃ will provide hysteresis if required.

Nonvolatile Low Voltage Detector (Figure 29)

In this application the high trip voltage V_{TR2} is set to be above the normal supply voltage range. On power up the initial condition is A. On momentarily closing switch S₁ the operating point changes to B and will remain at B until the supply voltage drops below V_{TR1}, at which time the output will revert to condition A. Note that state A is always retained if the supply voltage is reduced below V_{TR1} (even to zero volts) and then raised back to V_{NOM}.

Nonvolatile Power Supply Malfunction Recorder (Figure 30 and Figure 31)

In many systems a transient or an extended abnormal (or absence of a) supply voltage will cause a system failure. This failure may take the form of information lost in a volatile semiconductor memory stack, a loss of time in a timer or even possible irreversible damage to components if a supply voltage exceeds a certain value.

It is, therefore, necessary to be able to detect and store the fact that an **out-of-operating range** supply voltage condition

ICL8211, ICL8212

Low trip voltage

$$V_{TR1} = \left[\frac{(R_1 + R_2) \times 1.15 + 0.1V}{R_1} \right] \text{ volts}$$

High trip voltage

FIGURE 29. NON-VOLATILE LOW VOLTAGE INDICATOR

ICL8211, ICL8212

has occurred, even in the case where a supply voltage may have dropped to zero. Upon power up to the normal operating voltage this record must have been retained and easily interrogated. This could be important in the case of a transient power failure due to a faulty component or intermittent power supply, open circuit, etc., where direct observation of the failure is difficult.

A simple circuit to record an out of range voltage excursion may be constructed using an ICL8211, an ICL8212 plus a few resistors. This circuit will operate to 30V without exceeding the maximum ratings of the ICs. The two voltage limits defining the in range supply voltage may be set to any value between 2.0V and 30V.

The ICL8212 is used to detect a voltage, V_2 , which is the upper voltage limit to the operating voltage range. The ICL8211 detects the lower voltage limit of the operating voltage range, V_1 . Hysteresis is used with the ICL8211 so that the output can be stable in either state over the operating voltage range V_1 to V_2 by making V_3 - the upper trip point of the ICL8211 much higher in voltage than V_2 .

The output of the ICL8212 is used to force the output of the

ICL8211 into the ON state above V_2 . Thus there is no value of the supply voltage that will result in the output of the ICL8211 changing from the ON state to the OFF state. This may be achieved only by shorting out R_3 for values of supply voltage between V_1 and V_2 .

Constant Current Sources (Figure 32)

The ICL8212 may be used as a constant current source of value of approximately $25\mu\text{A}$ by connecting the THRESHOLD terminal to GROUND. Similarly the ICL8211 will provide a $130\mu\text{A}$ constant current source. The equivalent parallel resistance is in the tens of megohms over the supply voltage range of 2V to 30V. These constant current sources may be used to provide basing for various circuitry including differential amplifiers and comparators. See Typical Operating Characteristics for complete information.

Programmable Zener Voltage Reference (Figure 33)

The ICL8212 may be used to simulate a zener diode by connecting the OUTPUT terminal to the V_2 output and using a resistor network connected to the THRESHOLD terminal

FIGURE 30. NON-VOLATILE POWER SUPPLY MALFUNCTION RECORDER

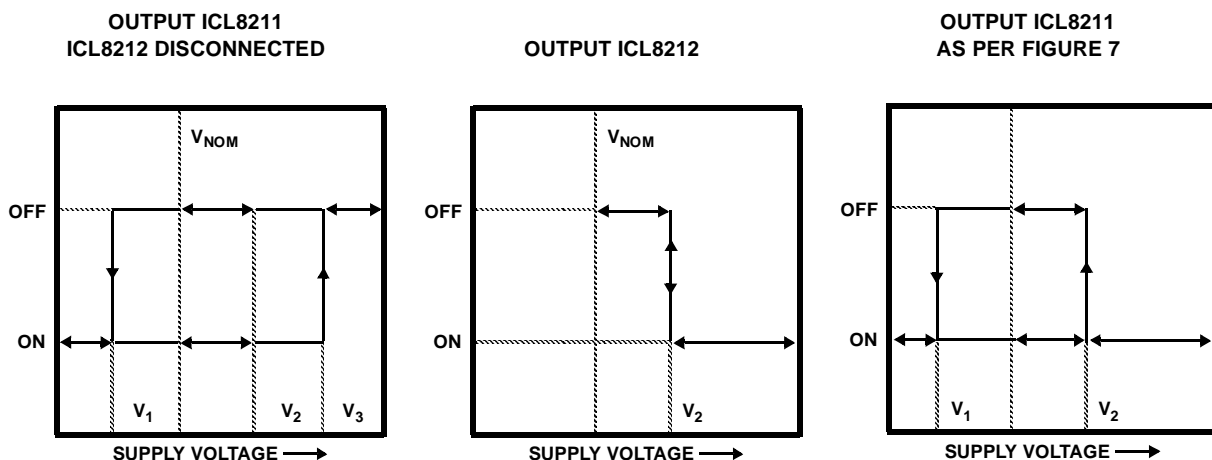

FIGURE 31. OUTPUT STATES OF THE ICL8211 AND ICL8212 AS A FUNCTION OF THE SUPPLY VOLTAGE

ICL8211, ICL8212

to program the zener voltage

$$V_{ZENER} = \frac{(R_1 + R_2)}{R_1} \times 1.15V.$$

Since there is no internal compensation in the ICL8212 it is necessary to use a large capacitor across the output to prevent oscillation.

Zener voltages from 2V to 30V may be programmed and typical impedance values between 300 μ A and 25 μ A will range from 4 Ω to 7 Ω . The knee is sharper and occurs at a significantly lower current than other similar devices available.

FIGURE 32. CONSTANT CURRENT SOURCE APPLICATIONS

FIGURE 33. PROGRAMMABLE ZENER VOLTAGE REFERENCE
Precision Voltage Regulator (Figure 34)

The ICL8212 may be used as the controller for a highly stable series voltage regulator. The output voltage is simply programmed, using a resistor divider network R_1 and R_2 . Two capacitors C_1 and C_2 are required to ensure stability since

the ICL8212 is uncompensated internally.

FIGURE 34. PRECISION VOLTAGE REGULATOR

This regulator may be used with lower input voltages than most other commercially available regulators and also consumes less power for a given output control current than any commercial regulator. Applications would therefore include battery operated equipment especially those operating at low voltages.

High Supply Voltage Dump Circuit (Figure 35)

In many circuit applications it is desirable to remove the power supply in the case of high voltage overload. For circuits consuming less than 5mA this may be achieved using an ICL8211 driving the load directly. For higher load currents it is necessary to use an external pnp transistor or darlington pair driven by the output of the ICL8211. Resistors R_1 and R_2 set up the disconnect voltage and R_3 provides optional voltage hysteresis if so desired.

FIGURE 35. HIGH VOLTAGE DUMP CIRCUITS

Frequency Limit Detector (Figure 36)

Simple frequency limit detectors providing a GO/NO-GO output for use with varying amplitude input signals may be conveniently implemented with the ICL8211/8212. In the

ICL8211, ICL8212

application shown, the first ICL8212 is used as a zero crossing detector. The output circuit consisting of R_3 , R_4 and C_2 results in a slow output positive ramp. The negative range is much faster than the positive range. R_5 and R_6 provide hysteresis so that under all circumstances the second ICL8212 is turned on for sufficient time to discharge C_3 . The time constant of $R_7 C_3$ is much greater than $R_4 C_2$. Depending upon the desired output polarities for low and high input frequencies, either an ICL8211 or an ICL8212 may be used as the output driver.

This circuit is sensitive to supply voltage variations and should be used with a stabilized power supply. At very low

frequencies the output will switch at the input frequency.

Switch Bounce Filter (Figure 37)

Single pole single throw (SPST) switches are less costly and more available than single pole double throw (SPDT) switches. SPST switches range from push button and slide types to calculator keyboards. A major problem with the use of switches is the mechanical bounce of the electrical contacts on closure. Contact bounce times can range from a fraction of a millisecond to several tens of milliseconds depending upon the switch type. During this contact bounce time the switch may make and break contact several times. The circuit shown in Figure 37 provides a rapid charge up of C_1 to close to the positive supply
