

# +2.5 V to +5.5 V, 230 $\mu$ A Dual Rail-to-Rail, Voltage Output 8-/10-/12-Bit DACs

## AD5302/AD5312/AD5322\*

### FEATURES

- AD5302: Two 8-Bit Buffered DACs in One Package**
- AD5312: Two 10-Bit Buffered DACs in One Package**
- AD5322: Two 12-Bit Buffered DACs in One Package**
- 10-Lead  $\mu$ SOIC Package**
- Micropower Operation: 300  $\mu$ A @ 5 V (Including Reference Current)**
- Power-Down to 200 nA @ 5 V, 50 nA @ 3 V**
- +2.5 V to +5.5 V Power Supply**
- Double-Buffered Input Logic**
- Guaranteed Monotonic By Design Over All Codes**
- Buffered/Unbuffered Reference Input Options**
- 0- $V_{REF}$  Output Voltage**
- Power-On-Reset to Zero Volts**
- Simultaneous Update of DAC Outputs via  $\overline{LDAC}$**
- Low Power Serial Interface with Schmitt-Triggered Inputs**
- On-Chip Rail-to-Rail Output Buffer Amplifiers**

### APPLICATIONS

- Portable Battery-Powered Instruments**
- Digital Gain and Offset Adjustment**
- Programmable Voltage and Current Sources**
- Programmable Attenuators**

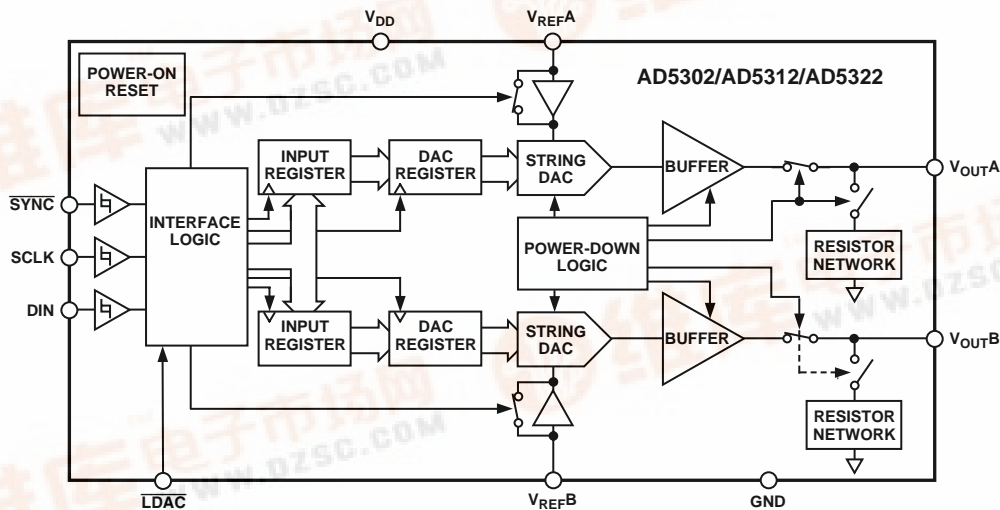

### GENERAL DESCRIPTION

The AD5302/AD5312/AD5322 are dual 8-, 10- and 12-bit buffered voltage output DACs in a 10-lead  $\mu$ SOIC package that operate from a single +2.5 V to +5.5 V supply consuming 230  $\mu$ A at 3 V. Their on-chip output amplifiers allow the outputs to swing rail-to-rail with a slew rate of 0.7 V/ $\mu$ s. The AD5302/AD5312/AD5322 utilize a versatile 3-wire serial interface which operates at clock rates up to 30 MHz and is compatible with standard SPI™, QSPI™, MICROWIRE™ and DSP interface standards.

The references for the two DACs are derived from two reference pins (one per DAC). The reference inputs may be configured as buffered or unbuffered inputs. The outputs of both DACs may be updated simultaneously using the asynchronous  $\overline{LDAC}$  input. The parts incorporate a power-on-reset circuit that ensures that the DAC outputs power-up to 0 V and remain there until a valid write takes place to the device. The parts contain a power-down feature that reduces the current consumption of the devices to 200 nA at 5 V (50 nA at 3 V) and provides software-selectable output loads while in power-down mode.

The low power consumption of these parts in normal operation make them ideally suited to portable battery operated equipment. The power consumption is 1.5 mW at 5 V, 0.7 mW at 3 V, reducing to 1  $\mu$ W in power-down mode.

## NOTES

<sup>1</sup>See Terminology.

<sup>2</sup>Temperature range: B Version:  $-40^{\circ}\text{C}$  to  $+105^{\circ}\text{C}$ .

<sup>3</sup>DC specifications tested with the outputs unloaded.

<sup>4</sup>Linearity is tested using a reduced code range: AD5302 (Code 8 to 248); AD5312 (Code 28 to 995); AD5322 (Code 115 to 3981).

<sup>5</sup>Guaranteed by design and characterization, not production tested.

<sup>6</sup>In order for the amplifier output to reach its minimum voltage, Offset Error must be negative. In order for the amplifier output to reach its maximum voltage,  $V_{REF} = V_{DD}$  and "Offset plus Gain" Error must be positive.

Specifications subject to change without notice.

## NOTES

<sup>1</sup>Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

<sup>2</sup>Transient currents of up to 100 mA will not cause SCR latch-up.

## PIN CONFIGURATION

## ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option	Branding Information
AD5302BRM	−40°C to +105°C	μSOIC	RM-10	D5B
AD5312BRM	−40°C to +105°C	μSOIC	RM-10	D6B
AD5322BRM	−40°C to +105°C	μSOIC	RM-10	D7B

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD5302/AD5312/AD5322 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN FUNCTION DESCRIPTIONS

Pin No.	Mnemonic	Function
1	$\overline{\text{LDAC}}$	Active low control input that transfers the contents of the input registers to their respective DAC registers. Pulsing this pin low allows either or both DAC registers to be updated if the input registers have new data. This allows simultaneous update of both DAC outputs
2	$V_{\text{DD}}$	Power Supply Input. These parts can be operated from +2.5 V to +5.5 V and the supply should be decoupled to GND.
3	$V_{\text{REFB}}$	Reference Input Pin for DAC B. This is the reference for DAC B. It may be configured as a buffered or an unbuffered input, depending on the BUF bit in the control word of DAC B. It has an input range from 0 V to $V_{\text{DD}}$ in unbuffered mode and from 1 V to $V_{\text{DD}}$ in buffered mode.
4	$V_{\text{REFA}}$	Reference Input Pin for DAC A. This is the reference for DAC A. It may be configured as a buffered or an unbuffered input depending on the BUF bit in the control word of DAC A. It has an input range from 0 V to $V_{\text{DD}}$ in unbuffered mode and from 1 V to $V_{\text{DD}}$ in buffered mode.
5	$V_{\text{OUTA}}$	Buffered Analog Output Voltage from DAC A. The output amplifier has rail-to-rail operation.
6	$V_{\text{OUTB}}$	Buffered Analog Output Voltage from DAC B. The output amplifier has rail-to-rail operation.
7	$\overline{\text{SYNC}}$	Active Low Control Input. This is the frame synchronization signal for the input data. When $\overline{\text{SYNC}}$ goes low, it powers on the SCLK and DIN buffers and enables the input shift register. Data is transferred in on the falling edges of the following 16 clocks. If $\overline{\text{SYNC}}$ is taken high before the 16th falling edge, the rising edge of $\overline{\text{SYNC}}$ acts as an interrupt and the write sequence is ignored by the device.
8	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input. Data can be transferred at rates up to 30 MHz. The SCLK input buffer is powered down after each write cycle.
9	DIN	Serial Data Input. This device has a 16-bit input shift register. Data is clocked into the register on the falling edge of the serial clock input. The DIN input buffer is powered down after each write cycle.
10	GND	Ground reference point for all circuitry on the part.

**TERMINOLOGY****RELATIVE ACCURACY**

For the DAC, relative accuracy or Integral Nonlinearity (INL) is a measure of the maximum deviation, in LSBs, from a straight line passing through the actual endpoints of the DAC transfer function. A typical INL vs. code plot can be seen in Figure 4.

**DIFFERENTIAL NONLINEARITY**

Differential Nonlinearity (DNL) is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of  $\pm 1$  LSB maximum ensures monotonicity. This DAC is guaranteed monotonic by design. A typical DNL vs. code plot can be seen in Figure 7.

**OFFSET ERROR**

This is a measure of the offset error of the DAC and the output amplifier. It is expressed as a percentage of the full-scale range.

**GAIN ERROR**

This is a measure of the span error of the DAC. It is the deviation in slope of the actual DAC transfer characteristic from the ideal expressed as a percentage of the full-scale range.

**OFFSET ERROR DRIFT**

This is a measure of the change in offset error with changes in temperature. It is expressed in (ppm of full-scale range)/°C.

**GAIN ERROR DRIFT**

This is a measure of the change in gain error with changes in temperature. It is expressed in (ppm of full-scale range)/°C.

**MAJOR-CODE TRANSITION GLITCH ENERGY**

Major-code transition glitch energy is the energy of the impulse injected into the analog output when the code in the DAC register changes state. It is normally specified as the area of the glitch in nV-secs and is measured when the digital code is changed by 1 LSB at the major carry transition (011 . . . 11 to 100 . . . 00 or 100 . . . 00 to 011 . . . 11).

**DIGITAL FEEDTHROUGH**

Digital feedthrough is a measure of the impulse injected into the analog output of the DAC from the digital input pins of the device, but is measured when the DAC is not being written to ( $\overline{\text{SYNC}}$  held high). It is specified in nV-secs and is measured with a full-scale change on the digital input pins, i.e., from all 0s to all 1s and vice versa.

**ANALOG CROSSTALK**

This is the glitch impulse transferred to the output of one DAC due to a change in the output of the other DAC. It is measured by loading one of the input registers with a full-scale code change (all 0s to all 1s and vice versa) while keeping  $\overline{\text{LDAC}}$  high. Then pulse  $\overline{\text{LDAC}}$  low and monitor the output of the DAC whose digital code was not changed. The area of the glitch is expressed in nV-secs.

# AD5302/AD5312/AD5322

## DAC-TO-DAC CROSSTALK

This is the glitch impulse transferred to the output of one DAC due to a digital code change and subsequent output change of the other DAC. This includes both digital and analog crosstalk. It is measured by loading one of the DACs with a full-scale code change (all 0s to all 1s and vice versa) while keeping  $\overline{\text{LDAC}}$  low and monitoring the output of the other DAC. The area of the glitch is expressed in nV-secs.

## DC CROSSTALK

This is the dc change in the output level of one DAC in response to a change in the output of the other DAC. It is measured with a full-scale output change on one DAC while monitoring the other DAC. It is expressed in  $\mu\text{V}$ .

## POWER-SUPPLY REJECTION RATIO (PSRR)

This indicates how the output of the DAC is affected by changes in the supply voltage. PSRR is the ratio of the change in  $V_{\text{OUT}}$  to a change in  $V_{\text{DD}}$  for full-scale output of the DAC. It is measured in dBs.  $V_{\text{REF}}$  is held at +2 V and  $V_{\text{DD}}$  is varied  $\pm 10\%$ .

## REFERENCE FEEDTHROUGH

This is the ratio of the amplitude of the signal at the DAC output to the reference input when the DAC output is not being updated (i.e.,  $\overline{\text{LDAC}}$  is high). It is expressed in dBs.

## TOTAL HARMONIC DISTORTION

This is the difference between an ideal sine wave and its attenuated version using the DAC. The sine wave is used as the reference for the DAC and the THD is a measure of the harmonics present on the DAC output. It is measured in dBs.

## MULTIPLYING BANDWIDTH

The amplifiers within the DAC have a finite bandwidth. The multiplying bandwidth is a measure of this. A sine wave on the reference (with full-scale code loaded to the DAC) appears on the output. The multiplying bandwidth is the frequency at which the output amplitude falls to 3 dB below the input.

## CHANNEL-TO-CHANNEL ISOLATION

This is a ratio of the amplitude of the signal at the output of one DAC to a sine wave on the reference input of the other DAC. It is measured in dBs.

# AD5302/AD5312/AD5322

## GENERAL DESCRIPTION

The AD5302/AD5312/AD5322 are dual resistor string DACs fabricated on a CMOS process with resolutions of 8, 10 and 12 bits, respectively. They contain reference buffers, output buffer amplifiers and are written to via a 3-wire serial interface. They operate from single supplies of +2.5 V to +5.5 V and the output buffer amplifiers provide rail-to-rail output swing with a slew rate of 0.7 V/μs. Each DAC is provided with a separate reference input, which may be buffered to draw virtually no current from the reference source, or unbuffered to give a reference input range from GND to V<sub>DD</sub>. The devices have three programmable power-down modes, in which one or both DACs may be turned off completely with a high impedance output, or the output may be pulled low by an on-chip resistor.

## Digital-to-Analog Section

The architecture of one DAC channel consists of a reference buffer and a resistor-string DAC followed by an output buffer amplifier. The voltage at the V<sub>REF</sub> pin provides the reference voltage for the DAC. Figure 26 shows a block diagram of the DAC architecture. Since the input coding to the DAC is straight binary, the ideal output voltage is given by:

$$V_{OUT} = \frac{V_{REF} \times D}{2^N}$$

where

D = decimal equivalent of the binary code that is loaded to the DAC register;

0–255 for AD5302 (8 Bits)

0–1023 for AD5312 (10 Bits)

0–4095 for AD5322 (12 Bits).

N = DAC resolution.

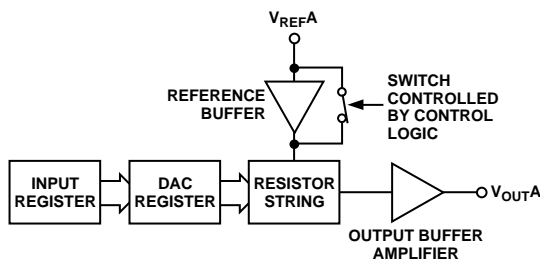

Figure 26. Single DAC Channel Architecture

## Resistor String

The resistor string section is shown in Figure 27. It is simply a string of resistors, each of value R. The digital code loaded to the DAC register determines at what node on the string the voltage is tapped off to be fed into the output amplifier. The voltage is tapped off by closing one of the switches connecting the string to the amplifier. Because it is a string of resistors, it is guaranteed monotonic.

Figure 27. Resistor String

## DAC Reference Inputs

There is a reference input pin for each of the two DACs. The reference inputs are buffered but can also be configured as unbuffered. The advantage with the buffered input is the high impedance it presents to the voltage source driving it.

However, if the unbuffered mode is used, the user can have a reference voltage as low as GND and as high as V<sub>DD</sub> since there is no restriction due to headroom and foot room of the reference amplifier.

If there is a buffered reference in the circuit (e.g., REF192) there is no need to use the on-chip buffers of the AD5302/AD5312/AD5322. In unbuffered mode the impedance is still large (180 kΩ per reference input).

The buffered/unbuffered option is controlled by the BUF bit in the control word (see Serial Interface section for a description of the register contents).

## Output Amplifier

The output buffer amplifier is capable of generating output voltages to within 1 mV of either rail which gives an output range of 0.001 V to V<sub>DD</sub> – 0.001 V when the reference is V<sub>DD</sub>. It is capable of driving a load of 2 kΩ in parallel with 500 pF to GND and V<sub>DD</sub>. The source and sink capabilities of the output amplifier can be seen in Figure 14.

The slew rate is 0.7 V/μs with a half-scale settling time to ±0.5 LSB (at 8 bits) of 6 μs. See Figure 19.

## POWER-ON RESET

The AD5302/AD5312/AD5322 are provided with a power-on reset function, so that they power up in a defined state. The power-on state is:

- Normal operation.
- Reference inputs unbuffered.
- Output voltage set to 0 V.

Both input and DAC registers are filled with zeros and remain so until a valid write sequence is made to the device. This is particularly useful in applications where it is important to know the state of the DAC outputs while the device is powering up.

## SERIAL INTERFACE

The AD5302/AD5312/AD5322 are controlled over a versatile, 3-wire serial interface, which operates at clock rates up to 30 MHz and is compatible with SPI, QSPI, MICROWIRE and DSP interface standards.

### Input Shift Register

The input shift register is 16 bits wide (see Figures 28–30 below). Data is loaded into the device as a 16-bit word under the control of a serial clock input, SCLK. The timing diagram for this operation is shown in Figure 1. The 16-bit word consists of four control bits followed by 8, 10 or 12 bits of DAC data, depending on the device type. The first bit loaded is the MSB (Bit 15), which determines whether the data is for DAC A or DAC B. Bit 14 determines if the reference input will be buffered or unbuffered. Bits 13 and 12 control the operating mode of the DAC.

**Table I. Control Bits**

Bit	Name	Function	Power-On Default
15	$\bar{A}/B$	0: Data Written to DAC A 1: Data Written to DAC B	N/A
14	BUF	0: Reference Is Unbuffered 1: Reference Is Buffered	0
13	PD1	Mode Bit	0
12	PD0	Mode Bit	0

Figure 28. AD5302 Input Shift Register Contents

Figure 29. AD5312 Input Shift Register Contents

Figure 30. AD5322 Input Shift Register Contents

The remaining bits are DAC data bits, starting with the MSB and ending with the LSB. The AD5322 uses all 12 bits of DAC data, the AD5312 uses 10 bits and ignores the 2 LSBs. The AD5302 uses eight bits and ignores the last four bits. The data format is straight binary, with all zeroes corresponding to 0 V output, and all ones corresponding to full-scale output ( $V_{REF} - 1 \text{ LSB}$ ).

The  $\overline{\text{SYNC}}$  input is a level-triggered input that acts as a frame synchronization signal and chip enable. Data can only be transferred into the device while  $\overline{\text{SYNC}}$  is low. To start the serial data transfer,  $\overline{\text{SYNC}}$  should be taken low observing the minimum  $\overline{\text{SYNC}}$  to SCLK active edge setup time,  $t_4$ . After  $\overline{\text{SYNC}}$  goes low, serial data will be shifted into the device's input shift register on the falling edges of SCLK for 16 clock pulses. Any data and clock pulses after the 16th will be ignored, and no further serial data transfer will occur until  $\overline{\text{SYNC}}$  is taken high and low again.

$\overline{\text{SYNC}}$  may be taken high after the falling edge of the 16th SCLK pulse, observing the minimum SCLK falling edge to  $\overline{\text{SYNC}}$  rising edge time,  $t_7$ .

After the end of serial data transfer, data will automatically be transferred from the input shift register to the input register of the selected DAC. If  $\overline{\text{SYNC}}$  is taken high before the 16th falling edge of SCLK, the data transfer will be aborted and the input registers will not be updated.

When data has been transferred into both input registers, the DAC registers of both DACs may be simultaneously updated, by taking  $\overline{\text{LDAC}}$  low.

### Low Power Serial Interface

To reduce the power consumption of the device even further, the interface only powers up fully when the device is being written to. As soon as the 16-bit control word has been written to the part, the SCLK and DIN input buffers are powered down. They only power-up again following a falling edge of  $\overline{\text{SYNC}}$ .

### Double-Buffered Interface

The AD5302/AD5312/AD5322 DACs all have double-buffered interfaces consisting of two banks of registers—input registers and DAC registers. The input register is connected directly to the input shift register and the digital code is transferred to the relevant input register on completion of a valid write sequence. The DAC register contains the digital code used by the resistor string.

Access to the DAC register is controlled by the  $\overline{\text{LDAC}}$  function. When  $\overline{\text{LDAC}}$  is high, the DAC register is latched and the input register may change state without affecting the contents of the DAC register. However, when  $\overline{\text{LDAC}}$  is brought low, the DAC register becomes transparent and the contents of the input register are transferred to it.

This is useful if the user requires simultaneous updating of both DAC outputs. The user may write to both input registers individually and then, by pulsing the  $\overline{\text{LDAC}}$  input low, both outputs will update simultaneously.

These parts contain an extra feature whereby the DAC register is not updated unless its input register has been updated since the last time that  $\overline{\text{LDAC}}$  was brought low. Normally, when  $\overline{\text{LDAC}}$  is brought low, the DAC registers are filled with the contents of the input registers. In the case of the AD5302/AD5312/AD5322, the part will only update the DAC register if the input register has been changed since the last time the DAC register was updated thereby removing unnecessary digital crosstalk.

## POWER-DOWN MODES

The AD5302/AD5312/AD5322 have very low power consumption, dissipating only 0.7 mW with a 3 V supply and 1.5 mW with a 5 V supply. Power consumption can be further reduced when the DACs are not in use by putting them into one of three power-down modes, which are selected by Bits 13 and 12 (PD1 and PD0) of the control word. Table II shows how the state of the bits corresponds to the mode of operation of that particular DAC.

**Table II. PD1/PD0 Operating Modes**

PD1	PD0	Operating Mode
0	0	Normal Operation
0	1	Power-Down (1 kΩ Load to GND)
1	0	Power-Down (100 kΩ Load to GND)
1	1	Power-Down (High Impedance Output)

When both bits are set to 0, the DACs work normally with their normal power consumption of 300 μA at 5 V. However, for the three power-down modes, the supply current falls to 200 nA at 5 V (50 nA at 3 V). Not only does the supply current drop but the output stage is also internally switched from the output of the amplifier to a resistor network of known values. This has the advantage that the output impedance of the part is known while the part is in power-down mode and provides a defined input condition for whatever is connected to the output of the DAC amplifier. There are three different options. The output is connected internally to GND through a 1 kΩ resistor, a 100 kΩ resistor or it is left open-circuited (Three-State). The output stage is illustrated in Figure 31.

The bias generator, the output amplifier, the resistor string and all other associated linear circuitry are all shut down when the power-down mode is activated. However, the contents of the registers are unaffected when in power-down. The time to exit power-down is typically 2.5 μs for  $V_{DD} = 5$  V and 5 μs when  $V_{DD} = 3$  V. See Figure 21 for a plot.

## MICROPROCESSOR INTERFACING

### AD5302/AD5312/AD5322 to ADSP-2101/ADSP-2103 Interface

Figure 32 shows a serial interface between the AD5302/AD5312/AD5322 and the ADSP-2101/ADSP-2103. The ADSP-2101/ADSP-2103 should be set up to operate in the SPORT Transmit Alternate Framing Mode. The ADSP-2101/ADSP-2103 SPORT is programmed through the SPORT control register and should be configured as follows: Internal Clock Operation, Active Low Framing, 16-Bit Word Length. Transmission is initiated by writing a word to the Tx register after the SPORT has been enabled. The data is clocked out on each falling edge of the DSP's serial clock and clocked into the AD5302/AD5312/AD5322 on the rising edge of the DSP's serial clock. This corresponds to the falling edge of the DAC's SCLK.

### AD5302/AD5312/AD5322 to 68HC11/68L11 Interface

Figure 33 shows a serial interface between the AD5302/AD5312/AD5322 and the 68HC11/68L11 microcontroller. SCK of the 68HC11/68L11 drives the SCLK of the AD5302/AD5312/AD5322, while the MOSI output drives the serial data line of the DAC. The SYNC signal is derived from a port line (PC7). The setup conditions for correct operation of this interface are as follows: the 68HC11/68L11 should be configured so that its CPOL bit is a 0 and its CPHA bit is a 1. When data is being transmitted to the DAC, the SYNC line is taken low (PC7). When the 68HC11/68L11 is configured as above, data appearing on the MOSI output is valid on the falling edge of SCK. Serial data from the 68HC11/68L11 is transmitted in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. Data is transmitted MSB first. In order to load data to the AD5302/AD5312/AD5322, PC7 is left low after the first eight bits are transferred, and a second serial write operation is performed to the DAC and PC7 is taken high at the end of this procedure.

## Bipolar Operation Using the AD5302/AD5312/AD5322

The AD5302/AD5312/AD5322 has been designed for single supply operation, but bipolar operation is also achievable using the circuit shown in Figure 38. The circuit shown has been configured to achieve an output voltage range of  $-5\text{ V} < V_{OUT} < +5\text{ V}$ . Rail-to-rail operation at the amplifier output is achievable using an AD820 or OP295 as the output amplifier.

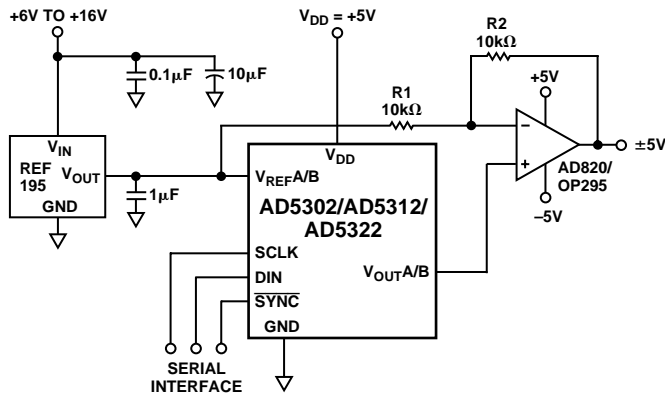

Figure 38. Bipolar Operation Using the AD5302/AD5312/AD5322

The output voltage for any input code can be calculated as follows:

$$V_{OUT} = [(V_{REF} \times D/2^N) \times (R1+R2)/R1 - V_{REF} \times (R2/R1)]$$

where

$D$  is the decimal equivalent of the code loaded to the DAC  
 $N$  is the DAC resolution

$V_{REF}$  is the reference voltage input.

with

$$V_{REF} = 5\text{ V}$$

$$R1 = R2 = 10\text{ k}\Omega \text{ and } V_{DD} = 5\text{ V}$$

$$V_{OUT} = (10 \times D/2^N) - 5\text{ V}$$

## Opto-Isolated Interface for Process Control Applications

The AD5302/AD5312/AD5322 has a versatile 3-wire serial interface, making it ideal for generating accurate voltages in process control and industrial applications. Due to noise, safety requirements or distance, it may be necessary to isolate the AD5302/AD5312/AD5322 from the controller. This can easily be achieved by using opto-isolators, which will provide isolation in excess of 3 kV. The serial loading structure of the AD5302/AD5312/AD5322 makes it ideally suited for use in opto-isolated applications. Figure 39 shows an opto-isolated interface to the AD5302/AD5312/AD5322 where DIN, SCLK and SYNC are driven from opto-couplers. The power supply to the part also needs to be isolated. This is done by using a transformer. On the DAC side of the transformer, a +5 V regulator provides the +5 V supply required for the AD5302/AD5312/AD5322.

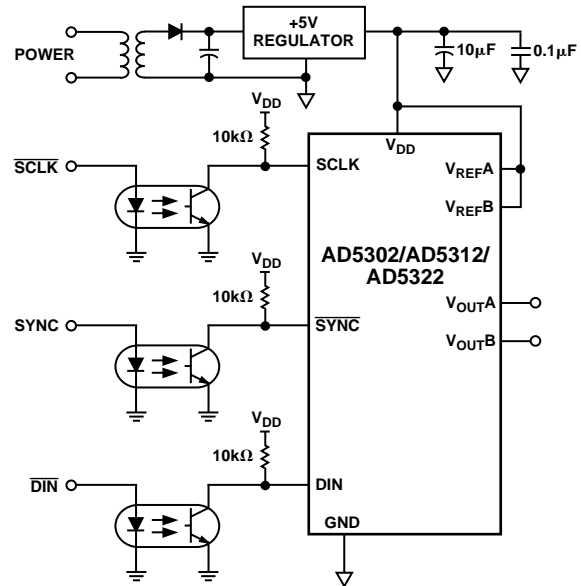

Figure 39. AD5302/AD5312/AD5322 in an Opto-Isolated Interface

## Decoding Multiple AD5302/AD5312/AD5322s

The SYNC pin on the AD5302/AD5312/AD5322 can be used in applications to decode a number of DACs. In this application, all the DACs in the system receive the same serial clock and serial data, but only the SYNC to one of the devices will be active at any one time allowing access to two channels in this eight-channel system. The 74HC139 is used as a 2-to-4 line decoder to address any of the DACs in the system. To prevent timing errors from occurring, the enable input should be brought to its inactive state while the coded address inputs are changing state. Figure 40 shows a diagram of a typical setup for decoding multiple AD5302/AD5312/AD5322 devices in a system.

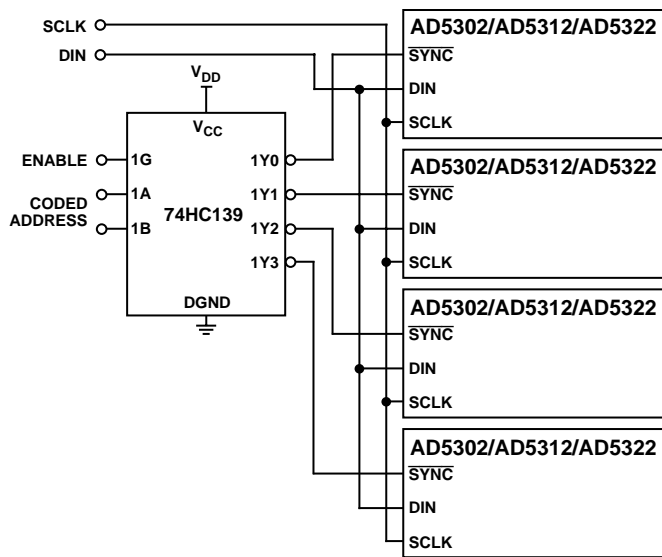

Figure 40. Decoding Multiple AD5302/AD5312/AD5322 Devices in a System

## AD5302/AD5312/AD5322 as a Digitally Programmable Window Detector

A digitally programmable upper/lower limit detector using the two DACs in the AD5302/AD5312/AD5322 is shown in Figure 41. The upper and lower limits for the test are loaded to DACs A and B which, in turn, set the limits on the CMP04. If the signal at the  $V_{IN}$  input is not within the programmed window, an LED will indicate the fail condition.

Figure 41. Window Detector Using AD5302/AD5312/AD5322

## Coarse and Fine Adjustment Using the AD5302/AD5312/AD5322

The DACs in the AD5302/AD5312/AD5322 can be paired together to form a coarse and fine adjustment function, as shown in Figure 42. DAC A is used to provide the coarse adjustment while DAC B provides the fine adjustment. Varying the ratio of R1 and R2 will change the relative effect of the coarse and fine adjustments. With the resistor values and external reference shown, the output amplifier has unity gain for the DAC A output, so the output range is 0 V to 2.5 V – 1 LSB. For DAC B the amplifier has a gain of  $7.6 \times 10^{-3}$ , giving DAC B a range equal to 19 mV.

The circuit is shown with a 2.5 V reference, but reference voltages up to  $V_{DD}$  may be used. The op amps indicated will allow a rail-to-rail output swing.

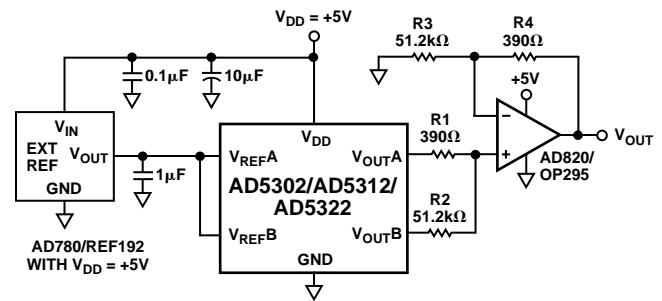

Figure 42. Coarse/Fine Adjustment

## Power Supply Bypassing and Grounding

In any circuit where accuracy is important, careful consideration of the power supply and ground return layout helps to ensure the rated performance. The printed circuit board on which the AD5302/AD5312/AD5322 is mounted should be designed so that the analog and digital sections are separated, and confined to certain areas of the board. If the AD5302/AD5312/AD5322 is in a system where multiple devices require an AGND-to-DGND connection, the connection should be made at one point only. The star ground point should be established as close as possible to the AD5302/AD5312/AD5322. The AD5302/AD5312/AD5322 should have ample supply bypassing of 10 μF in parallel with 0.1 μF on the supply located as close to the package as possible, ideally right up against the device. The 10 μF capacitors are the tantalum bead type. The 0.1 μF capacitor should have low Effective Series Resistance (ESR) and Effective Series Inductance (ESI), like the common ceramic types that provide a low impedance path to ground at high frequencies to handle transient currents due to internal logic switching.

The power supply lines of the AD5302/AD5312/AD5322 should use as large a trace as possible to provide low impedance paths and reduce the effects of glitches on the power supply line. Fast switching signals such as clocks should be shielded with digital ground to avoid radiating noise to other parts of the board, and should never be run near the reference inputs. Avoid crossover of digital and analog signals. Traces on opposite sides of the board should run at right angles to each other. This reduces the effects of feedthrough through the board. A microstrip technique is by far the best, but not always possible with a double-sided board. In this technique, the component side of the board is dedicated to ground plane while signal traces are placed on the solder side.
