## INTEGRATED CIRCUITS

## DATA SHEET

## TEA1205AT High efficiency DC／DC converter

## FEATURES

- Fully integrated DC/DC converter circuit
- Up conversion in 2 different modes
- High efficiency over wide load range
- Synchronizes to external high frequency clock
- Output power up to 3.6 W (typ.) continuous, 8 W in GSM burst mode
- Low quiescent power consumption
- True current limit for Li-ion battery compatibility
- Shut-down function
- 8-pin SO package.

## APPLICATIONS

- Cellular and cordless phones PDAs and others
- Supply voltage source for low-voltage chip sets
- Portable computers
- Battery backup supplies
- Cameras.

## GENERAL DESCRIPTION

The TEA1205AT (see Fig.1) is a fully integrated DC/DC converter circuit using the minimum amount of external components. It is intended to be used to supply electronic circuits with supply voltages of 3.3 or 5.5 V from 2,3 or 4 NiCd cell batteries or one Li-ion battery at an output power level up to 3.6 W (typ.) continuously, or 8 W in GSM TDMA $(1: 8)$ burst mode. The switching frequency of the converter can be synchronized to an external high-frequency clock. Efficient, compact and dynamic power conversion is achieved using a novel, digitally controlled Pulse Width and Frequency Modulation (PWFM) like control concept, integrated low $\mathrm{R}_{\mathrm{dsON}}$ CMOS power switches with low parasitic capacitances and synchronous rectification.

## Note

1. The NFET current limit is set by an external $1 \%$ accurate resistor $\mathrm{R}_{\text {lim }}$ connected between pin 7 and pin 6 (ground). The typical maximum instantaneous current is defined as: $l_{\text {lim }}=890 \mathrm{~V} / \mathrm{R}_{\text {lim }}$ so the use of $\mathrm{R}_{\text {lim }}=315 \Omega$ will lead to a typical maximum current value of 2.83 A . The average inductor current during current limit also depends on inductance value and resistive losses in all components in the power path. In normal application and when using $\mathrm{R}_{\text {lim }}=315 \Omega$, the average inductor current will be limited to 2.3 A typical.

## FUNCTIONAL DESCRIPTION

## Control mechanism

The TEA1205AT DC/DC converter is able to operate in discontinuous or continuous conduction operation. All switching actions are completely determined by a digital control circuit which uses the output voltage level as its control input. This novel digital approach enables the use of a new pulse width and frequency modulation scheme, which ensures optimum power efficiency over the complete range of operation of the converter. The scheme works as follows. At low output power, a very small current pulse is generated in the inductor, and the pulse rate varies with a varying load. When the output voltage drops below a specific limit, which indicates that the converter's current capability is not sufficient, the digital controller switches to the next state of operation. The peak current in the inductor is made higher, and the pulse rate can again vary with a varying load. A third operation state is available for again higher currents.

When high output power is requested, the device starts operating in continuous conduction mode. This results in minimum AC currents in the circuit components and hence optimum efficiency, cost, and EMC. In this mode, the output voltage is allowed to vary between two predefined voltage levels. As long as the output voltage stays within this so-called window, switching continues in a fixed pattern. When the output voltage reaches one of the window borders, the digital controller immediately reacts by adjusting the pulse width and inserting a current step in such a way that the output voltage stays within the window with higher or lower current capability. This approach enables very fast reaction to load variations. Figure 3 shows the various coil current waveforms for low and high current capability in each power conversion mode.

Figure 4 shows the converter's response to a sudden load increase. The upper trace shows the output voltage.

Fig. 2 Pin configuration.

The ripple on top of the DC level is a result of the current in the output capacitor, which changes in sign twice per cycle, times the capacitor's internal Equivalent Series Resistance (ESR). After each ramp-down of the inductor current, i.e. when the ESR effect increases the output voltage, the converter determines what to do in the next cycle. As soon as more load current is taken from the output the output voltage starts to decay. When the output voltage becomes lower than the low limit of the window, a corrective action is taken by a ramp-up of the inductor current during a much longer time. As a result, the DC current level is increased and normal continuous conduction mode can continue. The output voltage (including ESR effect) is again within the predefined window.

Figure 5 depicts the spread of the output voltage window. The absolute value is most dependent on spread, while the actual window size is not affected. For one specific device, the output voltage will not vary more than $4 \%$.

## Start-up

A possible deadlock situation in boost configuration can occur after a sequence of disconnecting and reconnecting the input voltage source. If, after disconnection of the input source, the output voltage falls below 2.0 V , the device may not restart properly after reconnection of the input source, and may take continuous current from the input.

An external circuit to prevent the deadlock situation is shown in Chapter "Application information".

## Shut-down

When the shut-down pin is made HIGH, the converter disables both switches and power consumption is reduced to a few $\mu \mathrm{A}$.

## Synchronisation function

In continuous conduction mode, the converter switching frequency is synchronized to the signal at the SYNC input, provided that this signal is present and its frequency is 13 MHz . The switching frequency will than be $2^{6}$ times smaller than the applied input frequency at the sync pin. If no sync signal is applied (Sync pin H or L), the converter's switching frequency will be around 203 kHz , equally to behaviour at 13 MHz sync input frequency, but with a larger tolerance. When this function is not used, the SYNC pin must be tied to pin 3 or pin 6.

## Power switches

The power switches in the IC are one N-type and one P-type MOSFET, having a typical pin-to-pin resistance of $0.12 \Omega$ and $0.16 \Omega$ respectively. The maximum average current in the switches is 1.0 A .

## Temperature protection

At too high device temperature (typical $165^{\circ} \mathrm{C}$ ), the converter stops operating. It resumes operation when the device temperature falls below $165^{\circ} \mathrm{C}$ again. As a result, low-frequent cycling between on and off state will occur. It should be noted that in the event of device temperatures around the cut-off limit, the application differs strongly from maximum specifications.

## Current limit

If the current in the N -type power switch exceeds the limit which is set by the value of the external resistor, current ramping is stopped immediately, and the next switching phase is entered. Current limitation is required to enable optimal use of energy in Li-ion batteries, and to keep power conversion efficient during temporary high loads. Furthermore, current limitation protects the IC against overload conditions, inductor saturation, etc.

## Behaviour at input voltage exceeding the specified range

In general, an input voltage exceeding the specified range is not recommended since instability may occur. However, at an input voltage equal to or higher than the target output voltage plus the diode voltage drop, but lower than 6 V , the converter will stop switching and the external schottky diode will take over, resulting in $\mathrm{V}_{0}$ equalling $\mathrm{V}_{\mathrm{i}}$ minus the diode voltage drop (see Fig.8).

Fig. 4 Response to load increase.

Fig. 5 Output voltage window position at typical, maximum and minimum specification.

## LIMITING VALUES

In accordance with the Absolute Maximum Rating System (IEC 134).

## Notes

1. The NFET current limit is set by an external $1 \%$ accurate resistor $R_{\text {lim }}$ connected between pin 7 and pin 6 (ground). The typical maximum instantaneous current is defined as: $l_{\text {lim }}=890 \mathrm{~V} / \mathrm{R}_{\text {lim }}$ so the use of $\mathrm{R}_{\text {lim }}=315 \Omega$ will lead to a typical maximum current value of 2.83 A . The average inductor current during current limit also depends on inductance value and resistive losses in all components in the power path. In normal application and when using $R_{\text {lim }}=315 \Omega$, the average inductor current will be limited to 2.3 A typical.
2. $\mathrm{V}_{3}$ is the voltage at pin 3 (OUT).
3. If the applied high level is less than $\mathrm{V}_{3}-1 \mathrm{~V}$, the quiescent current level of the device will increase. The maximum increase is $300 \mu \mathrm{~A}$ in the event that pin 2 is at 2.0 V .

Using a Coilcraft DO3308P $10 \mu \mathrm{H}$ inductor and a Sprague 595D $330 \mu \mathrm{~F}$ capacitor.
The dotted line represents the Pulse Frequency Modulation (PFM) and the solid line the Pulse Width Modulation (PWM).
Fig. 6 Efficiency as a function of load current $\mathrm{I}_{\mathrm{L}}(2.4$ to 3.3 V ).

## APPLICATION INFORMATION

Fig. 8 Complete application for upconversion.

A typical component choice for an upconverter from 3 NiCd cells or one Li-ion cell to 5.0 V in a GSM handset (peak power 7.5 W, peak current 2.7 A) is (see Fig.8):

- L1 = $10 \mu \mathrm{H}$; $\mathrm{I}_{\text {sat }}>2.3 \mathrm{~A}$; low DC resistance, e.g. Coilcraft DO3308-103
- C1 $=100 \mu \mathrm{~F}$; low ESR capacitor; necessity depends on type of input voltage source
- C2 $=330 \mu F ;$ ESR $=0.1 \Omega$; e.g. Sprague 595D series
- D1; medium power Schottky diode; e.g. Philips PRLL5819.

For lower power applications, the $I_{\text {sat }}$ and $R_{D C}$ values of the inductor can be scaled back by the scaling factor of the output current from the values above. The same holds for the ESR value of the output capacitor. A further improvement is increase of inductance and decrease of output capacitance.

An additional circuit to prevent start-up deadlock in upconversion is shown in Fig.9. The function of TR1, R1 and R2 is to put the converter into shut-down mode when the input source is suddenly disconnected. The circuit operates as follows. When $\mathrm{V}_{1}$ is present, TR1 conducts and the SHDWN pin is kept LOW. As soon as $V_{1}$ falls below 1 V , TR1 no longer conducts and the device is put into shut-down before $\mathrm{V}_{\mathrm{O}}$ falls below 2 V . In the event that a signal is available which indicates the presence of the input voltage source, this signal should be applied to the

SHDWN pin. TR1, R1 and R2 should be omitted in that case.

More application information can be found in the associated application note.

## SOLDERING

## Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "Data Handbook IC26; Integrated Circuit Packages" (order code 9398652 90011).

## Reflow soldering

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to $250^{\circ} \mathrm{C}$.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at $45^{\circ} \mathrm{C}$.

## Wave soldering

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is $260^{\circ} \mathrm{C}$, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than $150^{\circ} \mathrm{C}$ within 6 seconds. Typical dwell time is 4 seconds at $250^{\circ} \mathrm{C}$.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

## Repairing soldered joints

Fix the component by first soldering two diagonallyopposite end leads. Use only a low voltage soldering iron (less than 24 V ) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to $300^{\circ} \mathrm{C}$. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and $320^{\circ} \mathrm{C}$.

## DEFINITIONS

| Data sheet status |  |
| :--- | :--- |
| Objective specification | This data sheet contains target or goal specifications for product development. |
| Preliminary specification | This data sheet contains preliminary data; supplementary data may be published later. |
| Product specification | This data sheet contains final product specifications. |
| Limiting values |  |
| Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or <br> more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation <br> of the device at these or at any other conditions above those given in the Characteristics sections of the specification <br> is not implied. Exposure to limiting values for extended periods may affect device reliability. |  |
| Application information | Where application information is given, it is advisory and does not form part of the specification. |

## LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
