ADJUSTABLE LDO AND SWITCH WITH DUAL CURRENT LIMIT FOR USB HIGH-POWER PERIPHERAL POWER MANAGEMENT

FEATURES

- Complete Power Management Solution for USB High-Power Peripherals
- 250 mA Low-Dropout Regulator (LDO) With Enable and 325 mA (Typ) Current Limit
- LDO Supports 2.7 V to 5.5 V V_{IN} and 0.9 V to 3.3 V Adjustable V_{OUT}
- 40 m Ω (Typ) High-Side MOSFET With Dual Current Limit
- Undervoltage Lockout and Power Good for LDO and Switch
- CMOS- and TTL-Compatible Enable Inputs
- 85 μ A (Typ) Supply Current
- 5 μ A (Typ) Standby Supply Current
- Available in 14-Pin HTSSOP (PowerPAD™)
- –40°C to 85°C Ambient Temperature Range
- Alternative to TPS2148/58 3.3-V LDO With 3.3-V Switch and 5-V Switch

APPLICATIONS

- High-Power USB™ Peripherals
 - ADSL Modems
 - Digital Still and PC Cameras
 - Zip Drives
 - Speakers
- DSP Sequencing

DESCRIPTION

The TPS2140/41/50/51 is a USB 1.0 and 2.0 Specification-compatible IC containing a dual-current-limiting power switch and an adjustable low dropout regulator (LDO). Both the switch and LDO limit inrush current by controlling the turnon slew rate. The unique dual-current-limiting feature of the switch allows USB peripherals to utilize high-value capacitance at the output of the switch, while keeping the inrush current low. During turnon, the switch limits the current delivered to the capacitive load to less than 100 mA. When the output voltage from the switch reaches about 93% of the input voltage, the switch power good output goes high, and the switch current limit increases to 800mA (minimum), at which point higher current loads can be turned on. The higher current limit provides short circuit protection while allowing the peripheral to draw maximum current from the USB bus.

The switch and LDO function independently, providing flexibility in DSP applications requiring separate core and I/O voltages. For example, in a DSP application operating from a 3.3-V rail, the LDO can supply the DSP core voltage down to 0.9 V, while the switch powers the 3.3-V (typical) DSP I/O supply. If supply sequencing is required, the LDO power good output can be used to enable the switch.

AVAILABLE OPTIONS

T _A	DESCRIPTION	TARGET APPLICATION	PACKAGE AND PIN COUNT	PACKAGED DEVICES	
				ACTIVE LOW (SWITCH)	ACTIVE HIGH (SWITCH)
–40°C to 85°C	Adjustable LDO and 3.3 V switch with dual current limit	DSP	HTSSOP-14	TPS2140IPWP	TPS2150IPWP
	Adjustable LDO and 5 V switch with dual current limit	USB	HTSSOP-14	TPS2141IPWP	TPS2151IPWP

NOTE: All options available taped and reeled. Add an R suffix (e.g., TPS2140IPWPR)

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

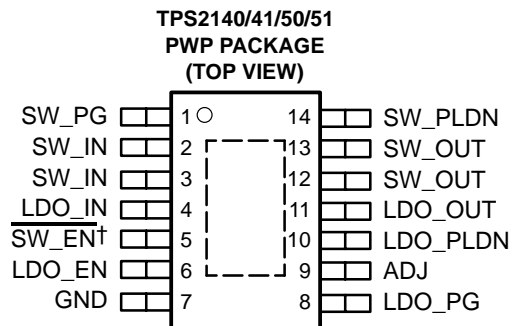

PowerPAD is a trademark of Texas Instruments.
USB is a trademark of Universal Serial Bus Association.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

† Pin 5 is active high for TPS2150 and TPS2151.

USB peripheral application

functional block diagram

† The pin is active low for TPS2140 and TPS2141, with an internal pullup.
The pin is active high for TPS2150 and TPS2151, with an internal pulldown.

Terminal Functions

TERMINAL NAME	NO.	I/O	DESCRIPTION
ADJ	9	I	Feedback adjustment of LDO regulator to set output voltage
GND	7		Ground
LDO_EN	6	I	Enable signal for LDO regulator, active high, no internal pullup or pulldown
LDO_IN	4	I	Input of LDO regulator
LDO_OUT	11	O	Output of LDO regulator
LDO_PG	8	O	Power good signal for LDO output, open-drain, active high
LDO_PLDN	10	I	Output pulldown pin used for LDO when connected to LDO_OUT
SW_EN or SW_EN	5	I	Active-high enable for switch on TPS2150 and TPS2151 devices with internal pulldown Active-low enable for switch on TPS2140 and TPS2141 devices with internal pullup
SW_IN	2, 3	I	Input of the switch
SW_OUT	12, 13	O	Output of switch
SW_PG	1	O	Power good signal for switch output, active high logic-level signal, no external pullup required.
SW_PLDN	14	I	Output pulldown pin used for switch when connected to SW_OUT.

detailed description

GND

Ground

SW_IN

SW_IN is the input to an integrated N-channel MOSFET, which has a maximum on-state resistance of 65 mΩ. Configured as a high-side switch, the power switch prevents current, flow from OUT to IN and IN to OUT when disabled. The power switch is rated at 500 mA, continuous current and has a dual current limit feature.

dual current limit

The current limiter for the switch limits the initial current drawn from SW_IN to 100 mA maximum. The user can estimate the amount of time it takes to charge a capacitor (CL) connected to SW_OUT by using the following relationship:

$$CL \times V_{I(SW_IN)} / 0.1 < t_{CHG} < CL \times V_{I(SW_IN)} / 0.05$$

Capacitance in farads. If $V_{I(SW_IN)} = 5$ V, then

$$50 \times CL < t_{CHG} < 100 \times CL$$

When the voltage at output SW_OUT rises above 93% of the voltage at SW_IN, the current limit is increased to 1800 mA maximum. The SW_PG can be used to turn on loads which may draw more than 50 mA.

In the event of an overload on SW_OUT, the protection circuit limits the current delivered to 1800 mA maximum. As the output voltage drops and it crosses 80% of the SW_IN voltage, the current limiter reverts back to the low-current limit mode of 100 mA maximum.

SW_IN also serves as one of the two inputs to an internal voltage selector that provides operating voltage to the whole device. The other input to the selector is LDO_IN.

SW_OUT

SW_OUT is the output of the internal power-distribution switch.

$\overline{SW_EN}$ or SW_EN

The logic input disables or enables the power switch. This signal is active low ($\overline{SW_EN}$) for TPS2140/41 and active high (SW_EN) for TPS2150/51. $\overline{SW_EN}$ has an internal pullup and SW_EN has an internal pulldown.

SW_PG

SW_PG signals the presence of an undervoltage condition on SW_OUT. The pin is driven by a CMOS output buffer and is pulled low during an undervoltage condition. To minimize erroneous SW_PG responses from transients on the voltage rail, the voltage sense circuit incorporates a rising and falling edge deglitch filter. When SW_OUT voltage is lower than 88% of 3.3 V for TPS2140/50, or 5 V for TPS2141/51, SW_PG goes low to indicate an undervoltage condition on SW_OUT.

SW_PLDN

SW_PLDN is an open drain output incorporated to provide a discharge path. When the power switch is on, this pin is open; otherwise it is pulled down to ground. When this pin is connected to SW_OUT, the output voltage fall time is reduced but the rise time remains unaffected.

LDO_IN

The LDO_IN serves as the input to the internal LDO. The adjustable LDO has a dropout voltage of 0.5 V maximum and is rated for 250 mA of continuous current. LDO_IN is also used as one of the two inputs for V_{CC} selection.

detailed description (continued)

LDO_OUT

LDO_OUT is the output of the internal LDO. It has an output voltage range of 0.9 V to 3.3 V.

LDO_EN

LDO_EN is used to enable or disable the internal LDO and is compatible with CMOS and TTL logic. LDO_EN is an active high input.

ADJ

ADJ is used to adjust the LDO output voltage (LDO_OUT) anywhere between 0.9 V and 3.3 V by connecting a resistor divider from LDO_OUT to ground (ADJ connects to the center point of the resistor divider).

LDO_PG

LDO_PG signals the presence of an undervoltage condition on LDO_OUT. LDO_PG is an open-drain output and is pulled low during an undervoltage condition. To minimize erroneous LDO_PG responses from transients on the voltage rail, the voltage sense circuit incorporates a 150- μ s falling deglitch filter. When the LDO_OUT voltage is lower than 94% of a threshold voltage (set by an external resistor divider), LDO_PG goes low to indicate an undervoltage condition. A pullup resistor from LDO_PG to a power rail is required for proper operation.

LDO_PLDN

LDO_PLDN is an open drain output incorporated to provide a discharge path. When the LDO is on, this pin is open; otherwise, it is pulled down to ground. When this pin is connected to LDO_OUT, the output voltage fall time is reduced but the rise time remains unaffected.

current sense

Both the power switch and the LDO have integrated current sense circuits. When an overload or short circuit is encountered, the current-sense circuitry sends a control signal to the driver. The driver reduces the gate voltage until the current drops back to the limiting value.

thermal sense

A dual-threshold thermal trip is implemented to protect the device. The lower thermal trip point is used to protect the device during an overcurrent condition. The higher thermal trip point is used to protect the device when the junction temperature rises but not due to an overcurrent condition.

undervoltage lockout

A voltage sense circuit monitors both input voltages on SW_IN and LDO_IN. When the input voltage is below its respective threshold, a control signal turns off the related channel (the power switch or the LDO).

APPLICATION INFORMATION

external capacitor requirements on power lines

Ceramic bypass capacitors (0.01 μF to 0.1 μF) between SW_IN and GND and LDO_IN and GND, close to the device, are recommended to improve load transient response and noise rejection. Bulk capacitors (4.7 μF or higher) between SW_IN and GND and LDO_IN and GND are also recommended, especially if load transients in the hundreds of milliamps with fast rise times are anticipated. A 66- μF bulk capacitor is recommended from SW_OUT to ground, especially when the output load is heavy. This precaution helps reduce transients seen on the power rails. Additionally, bypassing the outputs with a 0.1- μF ceramic capacitor improves the immunity of the device to short-circuit transients.

LDO output capacitor requirements

Stabilizing the internal control loop of the LDO requires an output capacitor connected between LDO_OUT and GND. The minimum recommended capacitance is 4.7 μF with an ESR value between 200 m Ω and 8.5 Ω . Solid tantalum electrolytic, aluminum electrolytic and multilayer ceramic capacitors are all suitable, provided they meet the ESR requirements (see Figures 15, 16, and 17). The adjustable LDO (for output voltages lower than 3 V) requires a bypass capacitor across the feedback resistor as shown in Figure 26. The nominal value of this capacitor is determined by using the following equation:

$$C_f = \frac{1}{(63.7 \times 10^3 \times 2 \times 3.14 \times R1)} - 4 \text{ pF} \quad (1)$$

where R1 is derived by programming the adjustable LDO (see programming the adjustable LDO regulator section shown below).

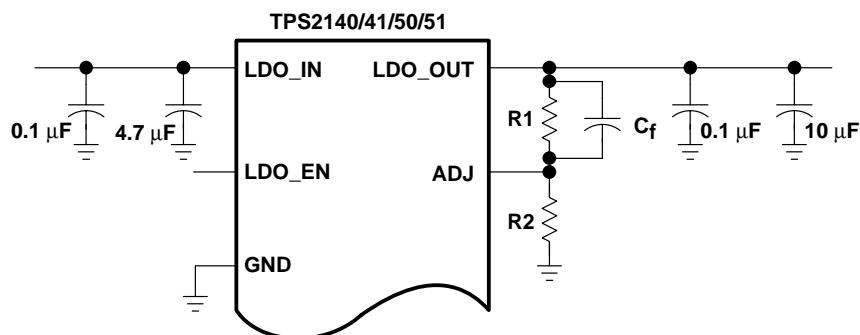

Figure 26. LDO External Resistor Divider

programming the adjustable LDO regulator

The output voltage of the TPS2140/41/50/51 adjustable regulator is programmed using an external resistor divider as shown in Figure 26. The output voltage is calculated using equation 2:

$$\text{LDO_OUT} = V_{\text{ref}} \left(1 + \frac{R1}{R2} \right) \quad (2)$$

where $V_{\text{ref}} = 0.8 \text{ V}$ typical (internal reference voltage).

Resistors R1 and R2 should be chosen for approximately 4- μA (minimum) divider current. Lower value resistors can be used but offer no inherent advantage and waste more power. Higher values should be avoided as a minimum load is required to sink the LDO forward leakage and maintain regulation. The recommended design procedure is to choose $R2 = 200 \text{ k}\Omega$ to set the divider current at 4- μA and then solve the LDO_OUT equation for R1.

APPLICATION INFORMATION

Table 1. Output Voltage Programming Guide

OUTPUT VOLTAGE	R1	R2	Cf
3.3	625 k Ω	200 k Ω	NR [†]
3.0	550 k Ω	200 k Ω	NR [†]
2.5	425 k Ω	200 k Ω	2 pF
1.8	250 k Ω	200 k Ω	6 pF
1.5	175 k Ω	200 k Ω	10.3 pF
1.0	50 k Ω	200 k Ω	46 pF

[†] NR – Not required

overcurrent

When an overcurrent condition is detected, the device maintains a constant output current. Complete shutdown occurs only if the fault is present long enough to activate thermal limiting.

Three possible overload conditions can occur. In the first condition, the output is shorted before the device is enabled. Once enabled the TPS2140/41/50/51 sense the short and immediately switch to a constant-current output.

In the second condition, the short occurs while the device is enabled. At the instant the short occurs, very high currents may flow for a very short time before the current-limit circuit can react. After the current-limit circuit has tripped (reached the overcurrent trip threshold), the device switches into constant-current mode.

In the third condition, the load has been gradually increased beyond the recommended operating current. The current is permitted to rise until the current-limit threshold is reached or until the thermal limit of the device is exceeded. The TPS2140/41/50/51 are capable of delivering current up to the current-limit threshold without damaging the device. Once the threshold has been reached, the device switches into its constant-current mode.

dual current limit

The TPS2140/41/50/51 has a dual-current-limited power switch. When the output voltage of the power switch is below a defined power-good threshold voltage, the typical current the switch can conduct is approximately 75 mA. Therefore, the inrush current can be limited to about 75 mA even if there is a very large capacitor on the load. When the switch output voltage reaches the power-good threshold voltage, the internal controller enables the higher current limit, which is at least 0.8 A and at most 1.8 A. This dual-current-limit feature completely solves the large inrush current problems that most power management applications experience. Figure 7 shows the inrush currents with different load capacitance. The current spike at $C_L = 600 \mu\text{F}$ is due to voltage difference between input and output once the higher current limit is enabled.

Because the lower current limit is only about 75 mA, the initial resistive load or equivalent load current on the switch output must be less than 50 mA, excluding the load capacitors.

APPLICATION INFORMATION

power dissipation and junction temperature

The major source of power dissipation for the TPS2140/41/50/51 comes from the internal voltage regulator and the N-channel MOSFET. Checking the power dissipation and junction temperature is always a good design practice and it starts with determining the $r_{DS(on)}$ of the N-channel MOSFET according to the input voltage and operating temperature. As an initial estimate, use the highest operating ambient temperature of interest and read $r_{DS(on)}$ from the graphs shown in the Typical Characteristics section of this data sheet. Using this value, the power dissipation per switch can be calculated using:

$$P_D = r_{DS(on)} \times I^2 \quad (3)$$

The power dissipation for the internal voltage regulator is calculated using:

$$P_D = (V_I - V_{O(min)}) \times I_O \quad (4)$$

The total power dissipation for the device becomes:

$$P_{D(total)} = P_{D(LDO)} + P_{D(switch)} \quad (5)$$

Finally, calculate the junction temperature:

$$T_J = P_D \times R_{\theta JA} + T_A \quad (6)$$

Where:

T_A = Ambient temperature °C

$R_{\theta JA}$ = Thermal resistance °C/W, equal to inverting the derating factor found on the power dissipation table in this data sheet.

Compare the calculated junction temperature with the initial estimate. If they do not agree within a few degrees, repeat the calculation, using the calculated value as the new estimate. Two or three iterations are generally sufficient to get a reasonable answer.

thermal protection

Thermal protection prevents damage to the IC when heavy-overload or short-circuit faults are present for extended periods of time. The overcurrent faults force the TPS2140/41/50/51 into constant-current mode at first, which causes the voltage across the high-side switch to increase; under short-circuit conditions, the voltage across the switch is equal to the input voltage. The increased dissipation causes the junction temperature to rise to high levels.

If either the power distribution switch or the LDO is in overcurrent, a thermal sensor trips at approximately 135°C, turning off both circuits. Normal operation resumes when the die temperature drops approximately 10°C. If neither the power distribution switch nor the LDO is in overcurrent, a second thermal sensor trips at approximately 160°C. Normal operation resumes when the die temperature drops approximately 10°C.

APPLICATION INFORMATION

undervoltage lockout (UVLO)

An undervoltage lockout ensures that the device (LDO and switch) is in the off state at power up. The UVLO also keeps the device from being turned on until the power supply has reached the start threshold (see undervoltage lockout table), even if the switches are enabled. The UVLO is also activated whenever the input voltage falls below the stop threshold as defined in the undervoltage lockout table. This function facilitates the design of hot-insertion systems where it is not possible to turn off the power switches before input power is removed. Upon reinsertion, the power switches are turned on with a controlled rise time to reduce EMI and voltage overshoots.

universal serial bus (USB) applications

The universal serial bus (USB) interface is a multiplexed serial bus operating at either 12 Mbps, or 1.5 Mbps for USB 1.1, or 480 Mbps for USB 2.0. The USB interface is designed to accommodate the bandwidth required by PC peripherals such as keyboards, printers, scanners, and mice. The four-wire USB interface was conceived for dynamic attach-detach (hot plug-unplug) of peripherals. Two lines are provided for differential data, and two lines are provided for 5-V power distribution.

USB data is a 3.3-V level signal, but power is distributed at 5 V to allow for voltage drops in cases where power is distributed through more than one hub across long cables. Each function must provide its own regulated 3.3 V from the 5-V input or its own internal power supply.

The USB specification defines the following five classes of devices, each differentiated by power-consumption requirements:

- Hosts/self-powered hubs (SPH)
- Bus-powered hubs (BPH)
- Low-power, bus-powered functions
- High-power, bus-powered functions
- Self-powered functions

The TPS2140/41/50/51 are well suited for USB hub and peripheral applications. The internal LDO can be used to provide the 3.3-V power needed by the controller while the switch distributes power to the downstream functions.

USB power-distribution requirements

USB can be implemented in several ways, and, regardless of the type of USB device being developed, several power-distribution features must be implemented.

- Hosts/self-powered hubs must:
 - Current-limit downstream ports
 - Report overcurrent conditions on USB VBUS
- Bus-powered hubs must:
 - Enable/disable power to downstream ports
 - Power up at <100 mA
 - Limit inrush current (<44 Ω and 10 μ F)
- Functions must:
 - Limit inrush currents
 - Power up at <100 mA

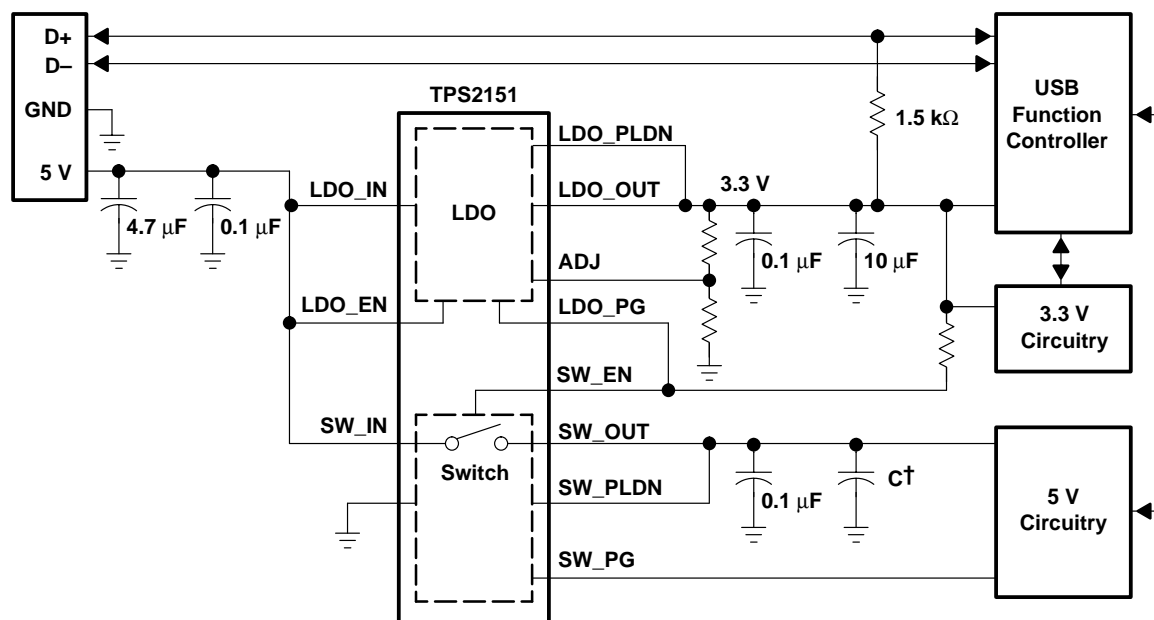

APPLICATION INFORMATION

USB power-distribution requirements (continued)

The feature set of the TPS2140/41/50/51 allows them to meet the requirements of functions. The integrated current-limiting is required by hubs and peripheral functions. The logic-level enable and controlled rise times meet the need of both input and output ports on bus-powered hubs, as well as the input ports for bus-powered functions.

USB applications

Figure 27 shows the TPS2151 being used in a USB bus-powered peripheral design. The internal 3.3-V LDO is used to provide power for the USB function controller as well as to the 1.5-k Ω pullup resistor. One example of USB bus-powered peripheral applications is the USB ADSL modem, which needs several power rails and power sequencing.

† C can be very high-value capacitance

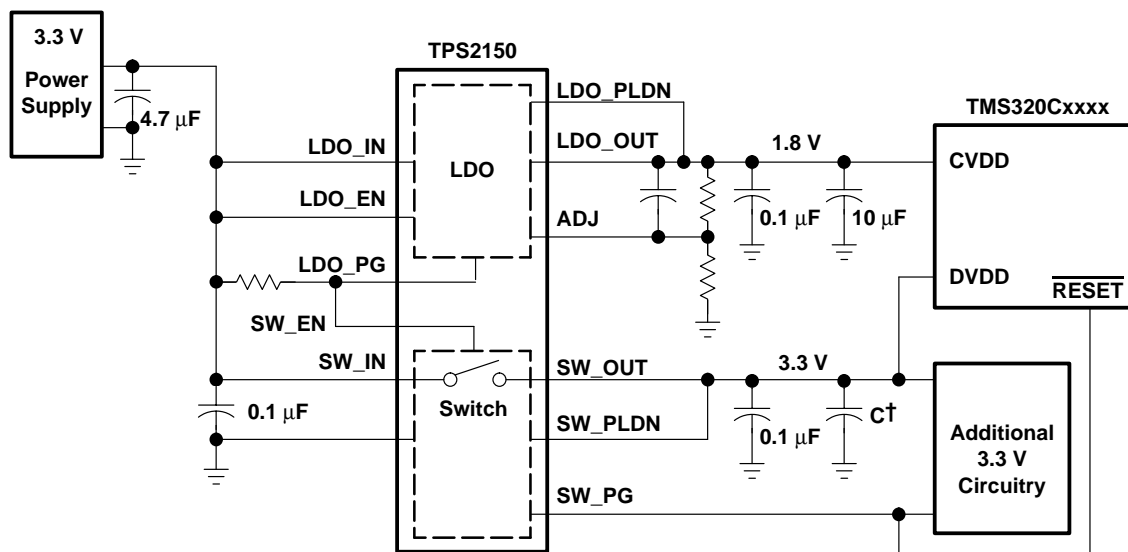

Figure 27. Bus-Powered USB Peripheral Application

APPLICATION INFORMATION

DSP applications

Figure 28 shows the TPS2150 in a DSP application. DSPs use 1.8-V core voltage and 3.3-V I/O voltage. In this type of application the TPS2150 adjustable LDO is configured for a 1.8-V output specifically for the DSP core voltage.

The additional 3.3-V circuitry is powered through the switch of the TPS2150 only after the DSP is up and running.

† C can be very high-value capacitance

Figure 28. DSP Power Sequencing Application

system level design consideration of DSP power application

System level design considerations, such as bus contention, may require supply sequencing to be implemented. In this case, the core supply should be powered up at the same time as (or prior to and powered down after), the I/O buffers. This is to ensure that the I/O buffers receive valid inputs from the core before the output buffers are powered up, thus preventing bus contention with other chips on the board.

For some DSP systems, the core supply may be required to provide a considerable amount of current until the I/O supply is powered up. This extra current condition is a result of uninitialized logic within the DSP(s). Decreasing the amount of time between the core supply power up and the I/O supply power up can minimize the effects of this current draw.
