

# IS42S16128

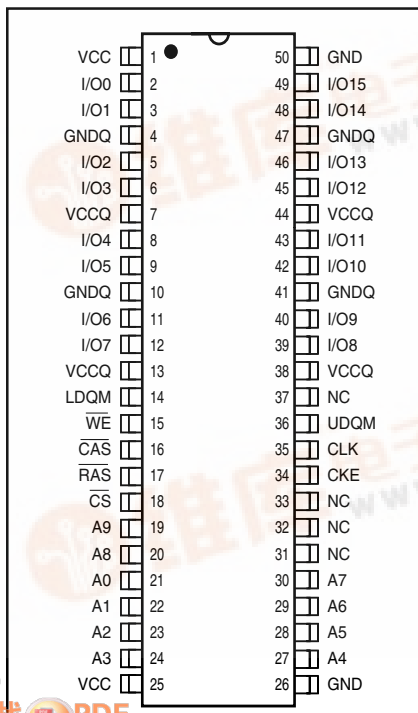

## 128K Words x 16 Bits x 2 Banks (4-MBIT) SYNCHRONOUS DYNAMIC RAM

FEBRUARY 2000

### FEATURES

- Clock frequency: 125 MHz, 100 MHz, 83 MHz
- Two banks can be operated simultaneously and independently
- Single 3.3V power supply
- LVTTTL interface
- Programmable burst length – (1, 2, 4, 8, full page)
- Programmable burst sequence: Sequential/Interleave
- Auto refresh, self refresh
- 1K refresh cycles every 16 ms
- Random column address every clock cycle
- Programmable  $\overline{\text{CAS}}$  latency (2, 3 clocks)
- Burst read/write and burst read/single write operations capability
- Byte controlled by LDQM and UDQM
- Package 400-mil 50-pin TSOP II

### PIN CONFIGURATIONS 50-Pin TSOP (Type II)

### DESCRIPTION

ISSI's 4Mb Synchronous DRAM IS42S16128 is organized as a 131072-word x 16-bit x 2-bank for improved performance. The synchronous DRAMs achieve high-speed data transfer using pipeline architecture. All inputs and outputs signals refer to the rising edge of the clock input.

### PIN DESCRIPTIONS

A0-A9	Address Input
A0-A8	Row Address Input
A9	Bank Select Address
A0-A7	Column Address Input
I/O0 to I/O15	Data I/O
CLK	System Clock Input
CKE	Clock Enable
$\overline{\text{CS}}$	Chip Select
$\overline{\text{RAS}}$	Row Address Strobe Command
$\overline{\text{CAS}}$	Column Address Strobe Command
$\overline{\text{WE}}$	Write Enable
LDQM	Lower Byte, Input/Output Mask
UDQM	Upper Byte, Input/Output Mask
Vcc	Power
GND	Ground
VccQ	Power Supply for I/O Pin
GNDQ	Ground for I/O Pin
NC	No Connection

### ORDERING INFORMATION

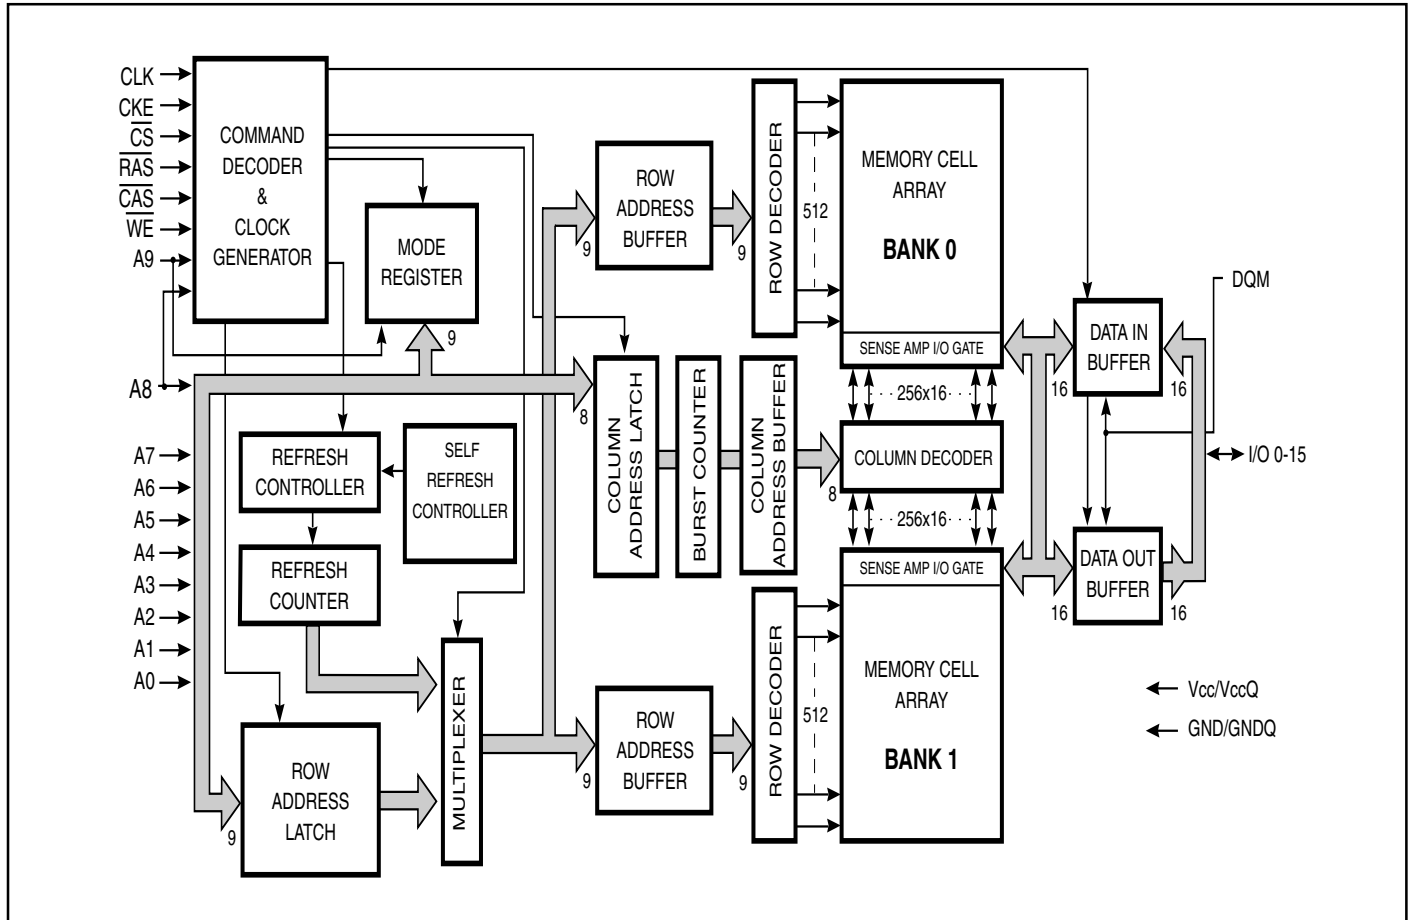

Commercial Range: 0-C to 70-C

Frequency	Speed (ns)	Order Part No.	Package
125 MHz	8	IS42S16128-8T	400-mil TSOP II
100 MHz	10	IS42S16128-10T	400-mil TSOP II
83 MHz	12	IS42S16128-12T	400-mil TSOP II

## PIN FUNCTIONS

Pin No.	Symbol	Type	Function (In Detail)
20 to 24, 27 to 30	A0-A8	Input Pin	A0 to A8 are address inputs. A0-A8 are used as row address inputs during active command input and A0-A7 as column address inputs during read or write command input. A8 is also used to determine the precharge mode during other commands. If A8 is LOW during precharge command, the bank selected by A9 is precharged, but if A8 is HIGH, both banks will be precharged. When A8 is HIGH in read or write command cycle, the precharge starts automatically after the burst access. These signals become part of the OP CODE during mode register set command input.
19	A9	Input Pin	A9 is the bank selection signal. When A9 is LOW, bank 0 is selected and when high, bank 1 is selected. This signal becomes part of the OP CODE during mode register set command input.
16	$\overline{\text{CAS}}$	Input Pin	$\overline{\text{CAS}}$ , in conjunction with the $\overline{\text{RAS}}$ and $\overline{\text{WE}}$ , forms the device command. See the "Command Truth Table" item for details on device commands.
34	CKE	Input Pin	The CKE input determines whether the CLK input is enabled within the device. When is CKE HIGH, the next rising edge of the CLK signal will be valid, and when LOW, invalid. When CKE is LOW, the device will be in either the power-down mode, the clock suspend mode, or the self refresh mode. The CKE is an asynchronous input.
35	CLK	Input Pin	CLK is the master clock input for this device. Except for CKE, all inputs to this device are acquired in synchronization with the rising edge of this pin.
18	$\overline{\text{CS}}$	Input Pin	The $\overline{\text{CS}}$ input determines whether command input is enabled within the device. Command input is enabled when $\overline{\text{CS}}$ is LOW, and disabled with $\overline{\text{CS}}$ is HIGH. The device remains in the previous state when $\overline{\text{CS}}$ is HIGH.
2, 3, 5, 6, 8, 9, 11 12, 39, 40, 42, 43, 45, 46, 48, 49	I/O0 to I/O15	I/O Pin	I/O0 to I/O15 are I/O pins. I/O through these pins can be controlled in byte units using the LDQM and UDQM pins.
14, 36	LDQM, UDQM	Input Pin	LDQM and UDQM control the lower and upper bytes of the I/O buffers. In read mode, LDQM and UDQM control the output buffer. When LDQM or UDQM is LOW, the corresponding buffer byte is enabled, and when HIGH, disabled. The outputs go to the HIGH impedance state when LDQM/UDQM is HIGH. This function corresponds to $\overline{\text{OE}}$ in conventional DRAMs. In write mode, LDQM and UDQM control the input buffer. When LDQM or UDQM is LOW, the corresponding buffer byte is enabled, and data can be written to the device. When LDQM or UDQM is HIGH, input data is masked and cannot be written to the device.
17	$\overline{\text{RAS}}$	Input Pin	$\overline{\text{RAS}}$ , in conjunction with $\overline{\text{CAS}}$ and $\overline{\text{WE}}$ , forms the device command. See the "Command Truth Table" item for details on device commands.
15	$\overline{\text{WE}}$	Input Pin	$\overline{\text{WE}}$ , in conjunction with $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ , forms the device command. See the "Command Truth Table" item for details on device commands.
7, 13, 38, 44	VccQ	Power Supply Pin	VccQ is the output buffer power supply.
1, 25	Vcc	Power Supply Pin	Vcc is the device internal power supply.
4, 10, 41, 47	GNDQ	Power Supply Pin	GNDQ is the output buffer ground.
26, 50	GND	Power Supply Pin	GND is the device internal ground.

FUNCTIONAL BLOCK DIAGRAM

**ABSOLUTE MAXIMUM RATINGS<sup>(1)</sup>**

Symbol	Parameters	Rating	Unit
V <sub>CC MAX</sub>	Maximum Supply Voltage	-1.0 to +4.6	V
V <sub>CCQ MAX</sub>	Maximum Supply Voltage for Output Buffer	-1.0 to +4.6	V
V <sub>IN</sub>	Input Voltage	-1.0 to +5.5	V
V <sub>OUT</sub>	Output Voltage	-1.0 to +4.6	V
P <sub>D MAX</sub>	Allowable Power Dissipation	1	W
I <sub>CS</sub>	Output Shorted Current	50	mA
T <sub>OPR</sub>	Operating Temperature	0 to +70	°C
T <sub>STG</sub>	Storage Temperature	-55 to +150	°C

**DC RECOMMENDED OPERATING CONDITIONS**At T<sub>A</sub> = 0 to +70°C<sup>(2)</sup>

Symbol	Parameter	Min.	Typ.	Max.	Unit
V <sub>CC</sub> , V <sub>CCQ</sub>	Supply Voltage	3.0	3.3	3.6	V
V <sub>IH</sub>	Input High Voltage	2.0	—	5.5	V
V <sub>IL</sub>	Input Low Voltage	-0.3	—	+0.8	V

**Note:**

1. Stress greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.
2. All voltages are referenced to GND.
3. V<sub>IH</sub> (max) = 5.5V for pulse width - 5 ns.
3. V<sub>IL</sub> (min) = -1.0V for pulse width - 5 ns.

**CAPACITANCE CHARACTERISTICS**At T<sub>A</sub> = 0 to +25°C, V<sub>CC</sub> = V<sub>CCQ</sub> = 3.3 ± 0.3V, f = 1 MHz<sup>(1,2)</sup>

Symbol	Parameter	Typ.	Max.	Unit
C <sub>IN1</sub>	Input Capacitance: A0-A9	—	5	pF
C <sub>IN2</sub>	Input Capacitance: (CLK, CE, $\overline{CS}$ , $\overline{RAS}$ , $\overline{CAS}$ , $\overline{WE}$ , LDQM, UDQM)	—	5	pF
CI/O	Data Input/Output Capacitance: I/O0-I/O15	—	7	pF

**DCELECTRICAL CHARACTERISTICS**

(Recommended Operation Conditions unless otherwise noted.)

I <sub>CC2PS</sub>			—	—	2	mA	
I <sub>CC2N</sub>	Precharge Standby Current (In Non Power-Down Mode)	CKE ≥ V <sub>IH</sub> (MIN) t <sub>CK</sub> = t <sub>CK</sub> (MIN) t <sub>CK</sub> = x	—	—	30	mA	
I <sub>CC2NS</sub>			—	—	15	mA	
I <sub>CC3P</sub>	Active Standby Current (In Power-Down Mode)	CKE ≤ V <sub>IL</sub> (MAX) t <sub>CK</sub> = t <sub>CK</sub> (MIN) t <sub>CK</sub> = x	—	—	3	mA	
I <sub>CC3PS</sub>			—	—	2	mA	
I <sub>CC3N</sub>	Active Standby Current (In Non Power-Down Mode)	CKE ≥ V <sub>IH</sub> (MIN) t <sub>CK</sub> = t <sub>CK</sub> (MIN) t <sub>CK</sub> = x	—	—	30	mA	
I <sub>CC3NS</sub>			—	—	15	mA	
I <sub>CC4</sub>	Operating Current (In Burst Mode) <sup>(1)</sup>	t <sub>CK</sub> = t <sub>CK</sub> (MIN) I <sub>OUT</sub> = 0mA	CAS latency = 3	-8	—	160	mA
				-10	—	160	mA
				-12	—	120	mA
			CAS latency = 2	-8	—	120	mA
				-10	—	120	mA
				-12	—	110	mA
I <sub>CC5</sub>	Auto-Refresh Current	t <sub>RC</sub> = t <sub>RC</sub> (MIN)	-8	—	100	mA	
			-10	—	100	mA	
			-12	—	80	mA	
I <sub>CC6</sub>	Self-Refresh Current	CKE ≤ 0.2V	—	—	2	mA	

**Notes:**

- These are the values at the minimum cycle time. Since the currents are transient, these values decrease as the cycle time increases. Also note that a bypass capacitor of at least 0.01 μF should be inserted between V<sub>CC</sub> and GND for each memory chip to suppress power supply voltage noise (voltage drops) due to these transient currents.
- I<sub>CC1</sub> and I<sub>CC4</sub> depend on the output load. The maximum values for I<sub>CC1</sub> and I<sub>CC4</sub> are obtained with the output open state.

AC CHARACTERISTICS<sup>(1,2,3)</sup>

Symbol	Parameter		-8		-10		-12		Units

t <sub>REF</sub>	Refresh Cycle Time		—	16	—	16	—	16	ms

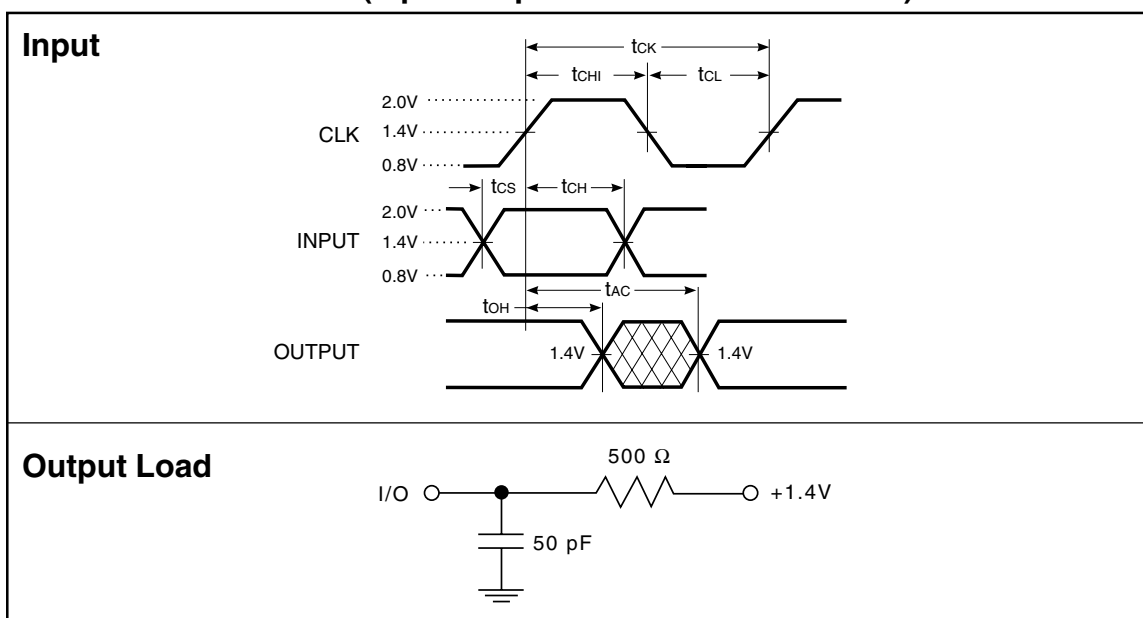

## Notes:

1. When power is first applied, memory operation should be started 100  $\mu$ s after V<sub>CC</sub> and V<sub>CCQ</sub> reach their stipulated voltages. Also note that the power-on sequence must be executed before starting memory operation.
2. Measured with t<sub>T</sub> = 1 ns.
3. The reference level is 1.4 V when measuring input signal timing. Rise and fall times are measured between V<sub>IH</sub> (min.) and V<sub>IL</sub> (max.).
4. Access time is measured at 1.4V with the load shown in the figure below.
5. The time t<sub>HZ</sub> (max.) is defined as the time required for the output voltage to transition by  $\pm$  200 mV from V<sub>OH</sub> (min.) or V<sub>OL</sub> (max.) when the output is in the high impedance state.

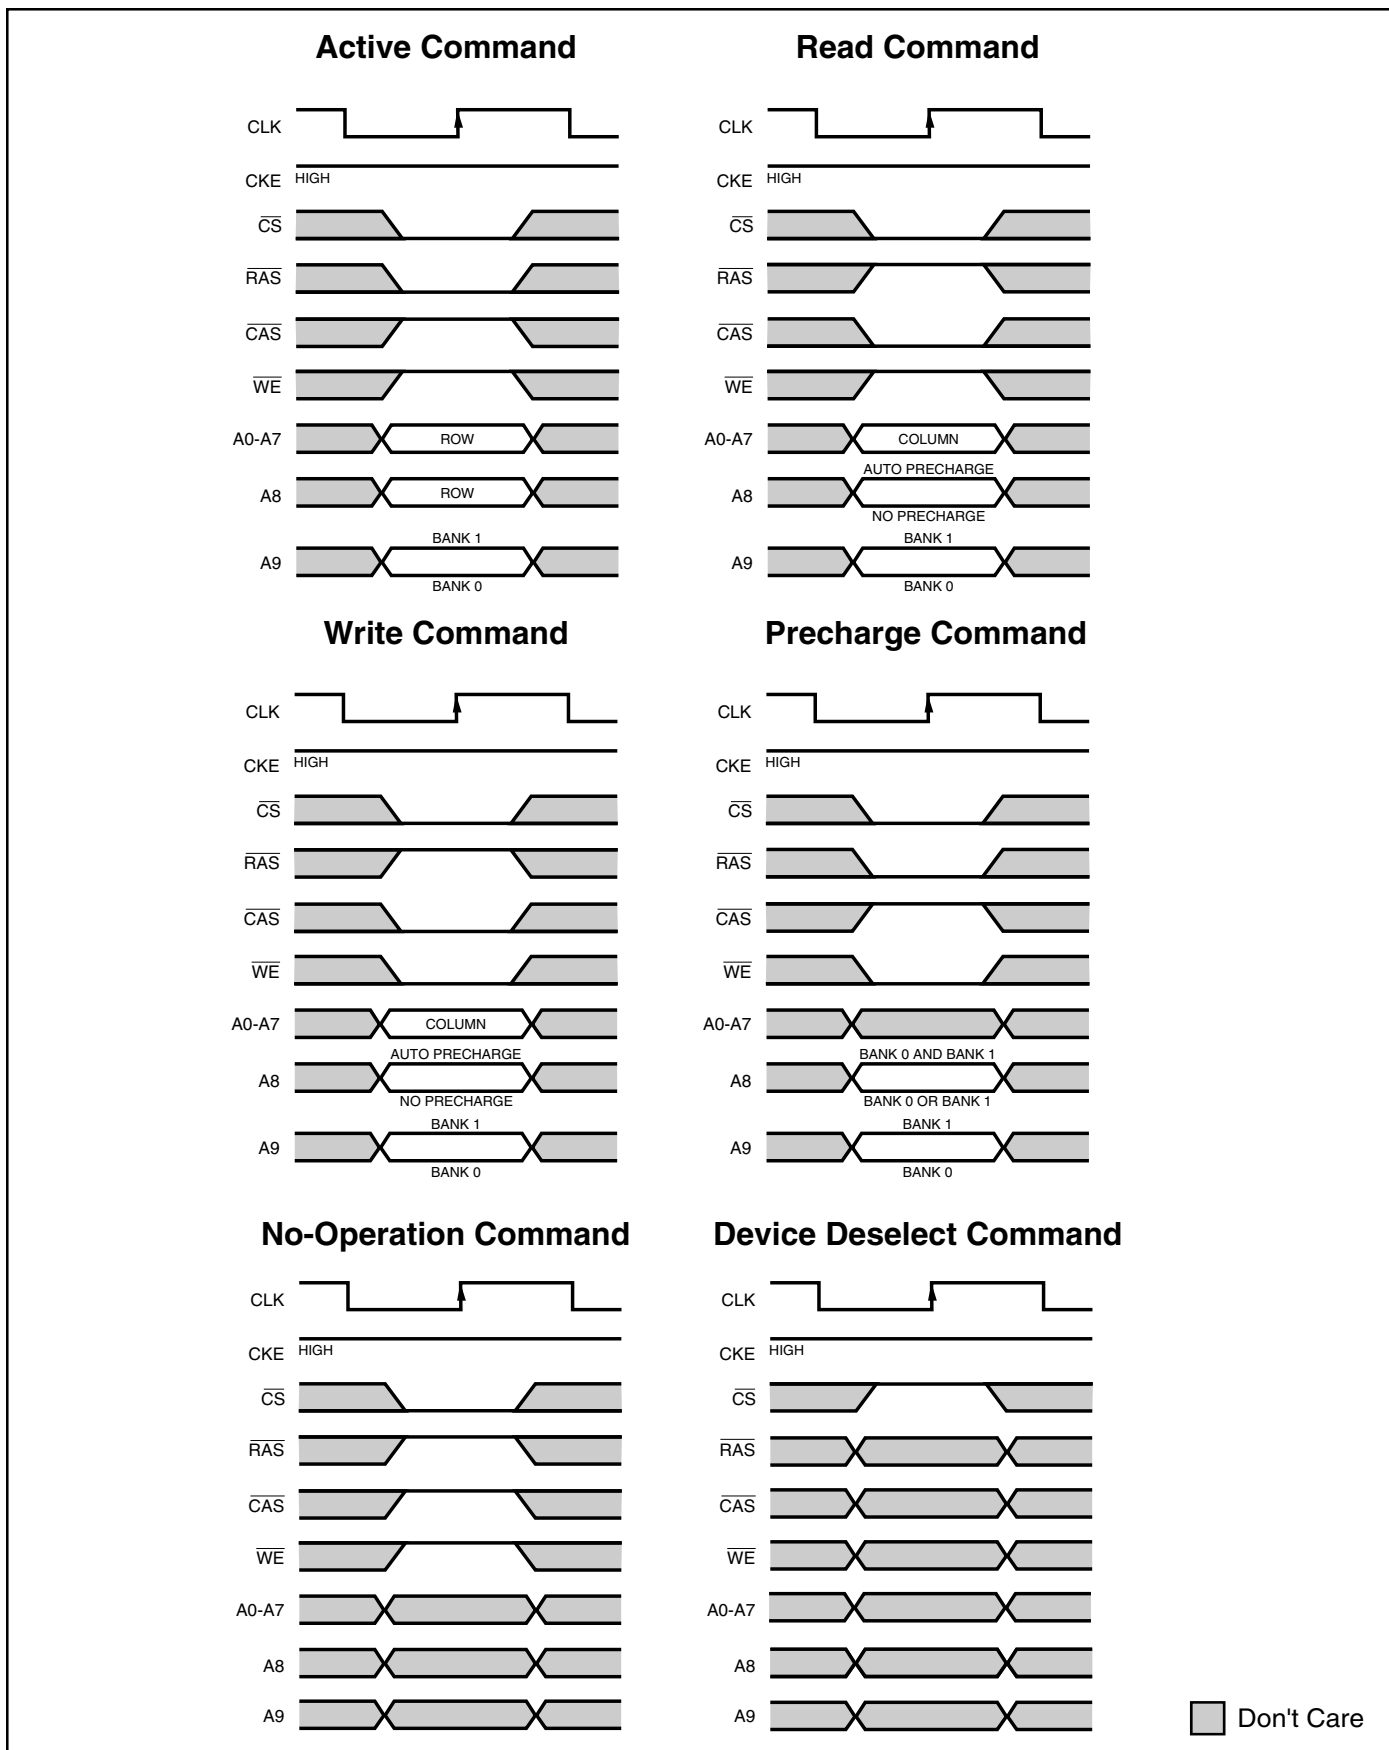

## OPERATING FREQUENCY / LATENCY RELATIONSHIPS

## AC TEST CONDITIONS (Input/Output Reference Level: 1.4V)

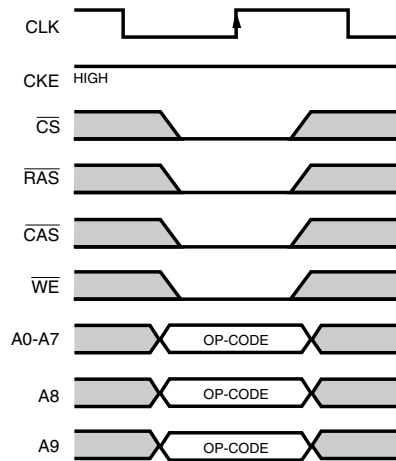

COMMANDS

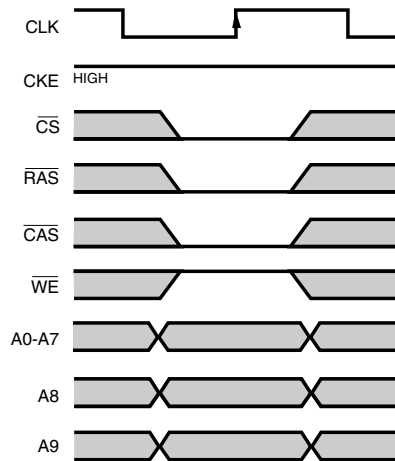

COMMANDS (cont.)

**Mode Register Set Command**

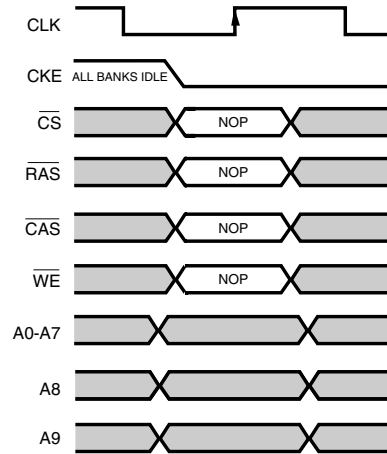

**Auto-Refresh Command**

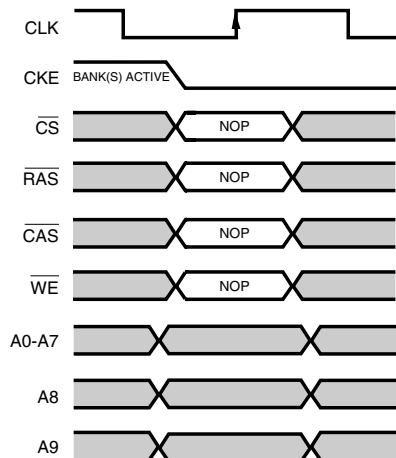

**Self-Refresh Command**

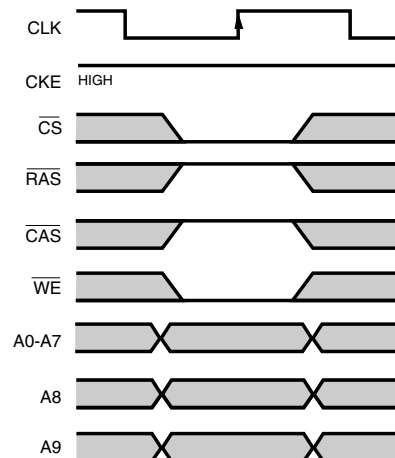

**Power Down Command**

**Clock Suspend Command**

**Burst Stop Command**

■ Don't Care

**Mode Register Set Command** $(\overline{CS}, \overline{RAS}, \overline{CAS}, \overline{WE} = \text{LOW})$ 

The IS42S16128 product incorporates a register that defines the device operating mode. This command functions as a data input pin that loads this register from the pins A0 to A9. When power is first applied, the stipulated power-on sequence should be executed and then the IS42S16128 should be initialized by executing a mode register set command.

Note that the mode register set command can be executed only when both banks are in the idle state, i.e., deactivated.

Another command cannot be executed after a mode register set command until after the passage of the period  $t_{MCD}$ , which is the period required for mode register set command execution.

**Active Command** $(\overline{CS}, \overline{RAS} = \text{LOW}, \overline{CAS}, \overline{WE} = \text{HIGH})$ 

The IS42S16128 includes two banks of 512 rows each. This command selects one of the two banks according to the A9 pin and activates the row selected by the pins A0 to A8.

This command corresponds to the fall of the  $\overline{RAS}$  signal from HIGH to LOW in conventional DRAMs.

**Precharge Command** $(\overline{CS}, \overline{RAS}, \overline{WE} = \text{LOW}, \overline{CAS} = \text{HIGH})$ 

This command starts precharging the bank selected by pins A8 and A9. When A8 is HIGH, both banks are precharged at the same time. When A8 is LOW, the bank selected by A9 is precharged. After executing this command, the next command for the selected bank(s) is executed after passage of the period  $t_{RP}$ , which is the period required for bank precharging.

This command corresponds to the  $\overline{RAS}$  signal from LOW to HIGH in conventional DRAMs

**Read Command** $(\overline{CS}, \overline{CAS} = \text{LOW}, \overline{RAS}, \overline{WE} = \text{HIGH})$ 

This command selects the bank specified by the A9 pin and starts a burst read operation at the start address specified by pins A0 to A7. Data is output following  $\overline{CAS}$  latency.

The selected bank must be activated before executing this command.

**Read Command (cont.)**

When the A8 pin is HIGH, this command functions as a read with auto-precharge command. After the burst read completes, the bank selected by pin A9 is precharged. When the A8 pin is LOW, the bank selected by the A9 pin remains in the activated state after the burst read completes.

**Write Command** $(\overline{CS}, \overline{CAS}, \overline{WE} = \text{LOW}, \overline{RAS} = \text{HIGH})$ 

When burst write mode has been selected with the mode register set command, this command selects the bank specified by the A9 pin and starts a burst write operation at the start address specified by pins A0 to A7. This first data must be input to the I/O pins in the cycle in which this command.

The selected bank must be activated before executing this command.

When A8 pin is HIGH, this command functions as a write with auto-precharge command. After the burst write completes, the bank selected by pin A9 is precharged. When the A8 pin is low, the bank selected by the A9 pin remains in the activated state after the burst write completes.

After the input of the last burst write data, the application must wait for the write recovery period ( $t_{DPL}$ ,  $t_{DAL}$ ) to elapse according to  $\overline{CAS}$  latency.

**Auto-Refresh Command** $(\overline{CS}, \overline{RAS}, \overline{CAS} = \text{LOW}, \overline{WE}, \text{CKE} = \text{HIGH})$ 

This command executes the auto-refresh operation. The row address and bank to be refreshed are automatically generated during this operation.

Both banks must be placed in the idle state before executing this command.

The stipulated period ( $t_{RC}$ ) is required for a single refresh operation, and no other commands can be executed during this period.

The device goes to the idle state after the internal refresh operation completes.

This command must be executed at least 1024 times every 16 ms.

This command corresponds to CBR auto-refresh in conventional DRAMs.

### Self-Refresh Command

( $\overline{\text{CS}}$ ,  $\overline{\text{RAS}}$ ,  $\overline{\text{CAS}}$ ,  $\text{CKE} = \text{LOW}$ ,  $\overline{\text{WE}} = \text{HIGH}$ )

This command executes the self-refresh operation. The row address to be refreshed, the bank, and the refresh interval are generated automatically internally during this operation. The self-refresh operation is started by dropping the CKE pin from HIGH to LOW. The self-refresh operation continues as long as the CKE pin remains LOW and there is no need for external control of any other pins. The self-refresh operation is terminated by raising the CKE pin from LOW to HIGH. The next command cannot be executed until the device internal recovery period ( $t_{\text{RC}}$ ) has elapsed. After the self-refresh, since it is impossible to determine the address of the last row to be refreshed, an auto-refresh should immediately be performed for all addresses (1024 cycles).

Both banks must be placed in the idle state before executing this command.

### Burst Stop Command

( $\overline{\text{CS}}$ ,  $\overline{\text{WE}}$ ,  $= \text{LOW}$ ,  $\overline{\text{RAS}}$ ,  $\overline{\text{CAS}} = \text{HIGH}$ )

The command forcibly terminates burst read and write operations. When this command is executed during a burst read operation, data output stops after the  $\overline{\text{CAS}}$  latency period has elapsed.

### No Operation

( $\overline{\text{CS}}$ ,  $= \text{LOW}$ ,  $\overline{\text{RAS}}$ ,  $\overline{\text{CAS}}$ ,  $\overline{\text{WE}} = \text{HIGH}$ )

This command has no effect on the device.

### Device Deselect Command

( $\overline{\text{CS}} = \text{HIGH}$ )

This command does not select the device for an object of operation. In other words, it performs no operation with respect to the device.

### Power-Down Command

( $\text{CKE} = \text{LOW}$ )

When both banks are in the idle (inactive) state, or when at least one of the banks is not in the idle (inactive) state, this command can be used to suppress device power dissipation by reducing device internal operations to the absolute minimum. Power-down mode is started by dropping the CKE pin from HIGH to LOW. Power-down mode continues as long as the CKE pin is held low.

### Power-Down Command (cont.)

All pins other than the CKE pin are invalid and none of the other commands can be executed in this mode. The power-down operation is terminated by raising the CKE pin from LOW to HIGH. The next command cannot be executed until the recovery period ( $t_{\text{CKA}}$ ) has elapsed.

Since this command differs from the self-refresh command described above in that the refresh operation is not performed automatically internally, the refresh operation must be performed within the refresh period ( $t_{\text{REF}}$ ). Thus the maximum time that power-down mode can be held is just under the refresh cycle time.

### Clock Suspend

( $\text{CKE} = \text{LOW}$ )

This command can be used to stop the device internal clock temporarily during a read or write cycle. Clock suspend mode is started by dropping the CKE pin from HIGH to LOW. Clock suspend mode continues as long as the CKE pin is held LOW. All input pins other than the CKE pin are invalid and none of the other commands can be executed in this mode. Also note that the device internal state is maintained. Clock suspend mode is terminated by raising the CKE pin from LOW to HIGH, at which point device operation restarts. The next command cannot be executed until the recovery period ( $t_{\text{CKA}}$ ) has elapsed.

Since this command differs from the self-refresh command described above in that the refresh operation is not performed automatically internally, the refresh operation must be performed within the refresh period ( $t_{\text{REF}}$ ). Thus the maximum time that clock suspend mode can be held is just under the refresh cycle time.

COMMAND TRUTH TABLE<sup>(1,2)</sup>

**Notes:**

1. H: HIGH level input, L: LOW level input, X: HIGH or LOW level input, V: Valid data input
2. All input signals are latched on the rising edge of the CLK signal.
3. Both banks must be placed in the inactive (idle) state in advance.
4. The state of the A0 to A9 pins is loaded into the mode register as an OP code.
5. The row address is generated automatically internally at this time. The I/O pin and the address pin data is ignored.
6. During a self-refresh operation, all pin data (states) other than CKE is ignored.
7. The selected bank must be placed in the inactive (idle) state in advance.
8. The selected bank must be placed in the active state in advance.
9. This command is valid only when the burst length set to full page.
10. This is possible depending on the state of the bank selected by the A9 pin.
11. Time to switch internal busses is required.
12. The IS42S16128 can be switched to power-down mode by dropping the CKE pin LOW when both banks in the idle state. Input pins other than CKE are ignored at this time.
13. The IS42S16128 can be switched to self-refresh mode by dropping the CKE pin LOW when both banks in the idle state. Input pins other than CKE are ignored at this time.
14. Possible if  $t_{RRD}$  is satisfied.
15. Illegal if  $t_{RAS}$  is not satisfied.
16. The conditions for burst interruption must be observed. Also note that the IS42S16128 will enter the precharged state immediately after the burst operation completes if auto-precharge is selected.
17. Command input becomes possible after the period  $t_{RCD}$  has elapsed. Also note that the IS42S16128 will enter the precharged state immediately after the burst operation completes if auto-precharge is selected.

W	Write
RP	Read With Auto-Precharge
WP	Write With Auto-Precharge
Any	Any State

SIMPLIFIED STATE TRANSITION DIAGRAM (One Bank Operation)

## Device Initialization At Power-On

(Power-On Sequence)

As is the case with conventional DRAMs, the IS42S16128 product must be initialized by executing a stipulated power-on sequence after power is applied.

After power is applied and  $V_{CC}$  and  $V_{CCQ}$  reach their stipulated voltages, set and hold the CKE and DQM pins HIGH for 100  $\mu$ s. Then, execute the precharge command to precharge both bank. Next, execute the auto-refresh command twice or more and define the device operation mode by executing a mode register set command.

The mode register set command can be also set before auto-refresh command.

## Mode Register Settings

The mode register set command sets the mode register. When this command is executed, pins A0 to A7, A8, and A9 function as data input pins for setting the register, and this data becomes the device internal OP code. This OP code has four fields as listed in the table below.

Input Pin	Field
A9, A8, A7	Write Mode
A6, A5, A4	$\overline{\text{CAS}}$ Latency
A3	Burst Type
A2, A1, A0	Burst Length

Note that the mode register set command can be executed only when both banks are in the idle (inactive) state. Wait at least two cycles after executing a mode register set command before executing the next command.

## $\overline{\text{CAS}}$ Latency

During a read operation, the between the execution of the read command and data output is stipulated as the  $\overline{\text{CAS}}$  latency. This period can be set using the mode register set command. The optimal  $\overline{\text{CAS}}$  latency is determined by the clock frequency and device speed grade. See the "Operating Frequency / Latency Relationships" item for details on the relationship between the clock frequency and the  $\overline{\text{CAS}}$  latency. See the table on the next page for details on setting the mode register.

## Burst Length

When writing or reading, data can be input or output data continuously. In these operations, an address is input only once and that address is taken as the starting address internally by the device. The device then automatically generates the following address. The burst length field in the mode register stipulates the number of data items input or output in sequence. In the IS42S16128 product, a burst length of 1, 2, 4, 8, or full page can be specified. See the table on the next page for details on setting the mode register.

## Burst Type

The burst data order during a read or write operation is stipulated by the burst type, which can be set by the mode register set command. The IS42S16128 product supports sequential mode and interleaved mode burst type settings. See the table on the next page for details on setting the mode register. See the "Burst Length and Column Address Sequence" item for details on I/O data orders in these modes.

## Write Mode

Burst write or single write mode is selected by the OP code (A9, A8, A7) of the mode register.

A burst write operation is enabled by setting the OP code (A9, A8, A7) to (0,0,0). A burst write starts on the same cycle as a write command set. The write start address is specified by the column address and bank select address at the write command set cycle.

A single write operation is enabled by setting OP code (A9, A8, A7) to (1,0,0). In a single write operation, data is only written to the column address and bank select address specified by the write command set cycle without regard to the burst length setting.

MODE REGISTER

Address Bus

## Burst Read

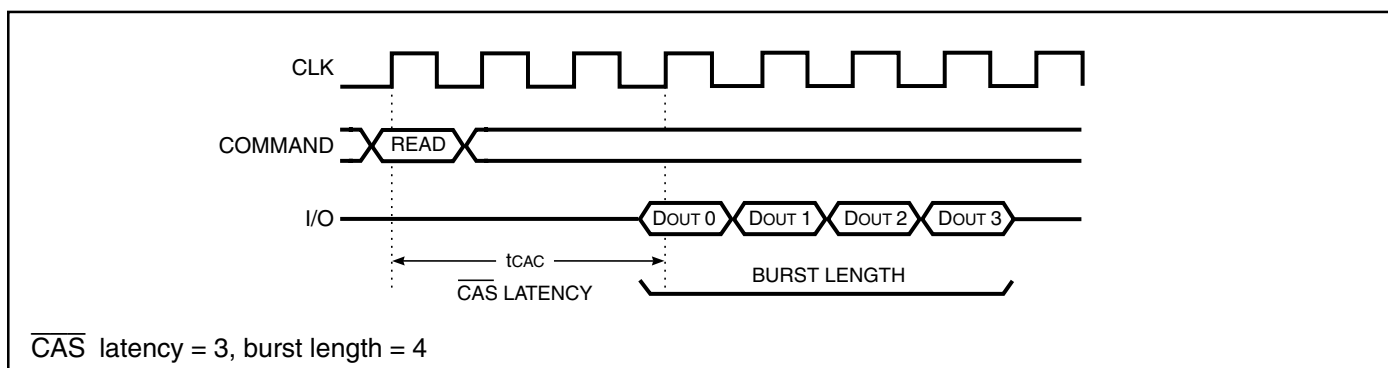

The read cycle is started by executing the read command. The address provided during read command execution is used as the starting address. First, the data corresponding to this address is output in synchronization with the clock signal after the  $\overline{\text{CAS}}$  latency period. Next, data corresponding to an address generated automatically by the device is output in synchronization with the clock signal.

The output buffers go to the LOW impedance state  $\overline{\text{CAS}}$  latency minus one cycle after the read command, and go to the HIGH impedance state automatically after the last data is output. However, the case where the burst length

is a full page is an exception. In this case the output buffers must be set to the high impedance state by executing a burst stop command.

Note that upper byte and lower byte output data can be masked independently under control of the signals applied to the U/LDQM pins. The delay period ( $t_{\text{MD}}$ ) is fixed at two, regardless of the  $\overline{\text{CAS}}$  latency setting, when this function is used.

The selected bank must be set to the active state before executing this command.

## Burst Write

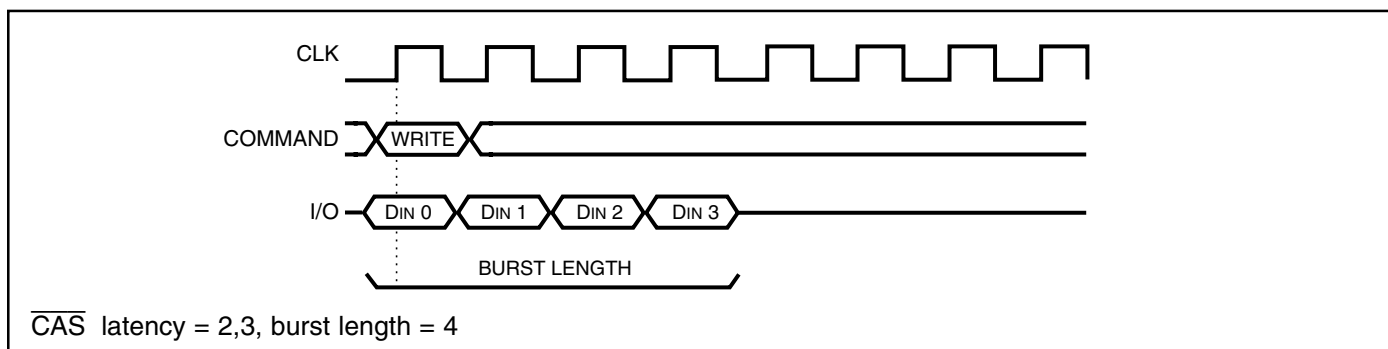

The write cycle is started by executing the command. The address provided during write command execution is used as the starting address, and at the same time, data for this address is input in synchronization with the clock signal.

Next, data is input in other in synchronization with the clock signal. During this operation, data is written to address generated automatically by the device. This cycle terminates automatically after a number of clock cycles determined by the stipulated burst length. However, the case where the burst length is a full page is an exception. In this case the write cycle must be terminated by executing a burst stop command.

The latency for I/O pin data input is zero, regardless of the  $\overline{\text{CAS}}$  latency setting. However, a wait period (write recovery:  $t_{\text{DPL}}$ ) after the last data input is required for the device to complete the write operation.

Note that the upper byte and lower byte input data can be masked independently under control of the signals applied to the U/LDQM pins. The delay period ( $t_{\text{MD}}$ ) is fixed at zero, regardless of the  $\overline{\text{CAS}}$  latency setting, when this function is used.

The selected bank must be set to the active state before executing this command.

**Read With Auto-Precharge**

The read with auto-precharge command first executes a burst read operation and then puts the selected bank in the precharged state automatically. After the precharge completes, the bank goes to the idle state. Thus this command performs a read command and a precharge command in a single operation.

During this operation, the delay period ( $t_{PQL}$ ) between the last burst data output and the start of the precharge operation differs depending on the  $\overline{\text{CAS}}$  latency setting.

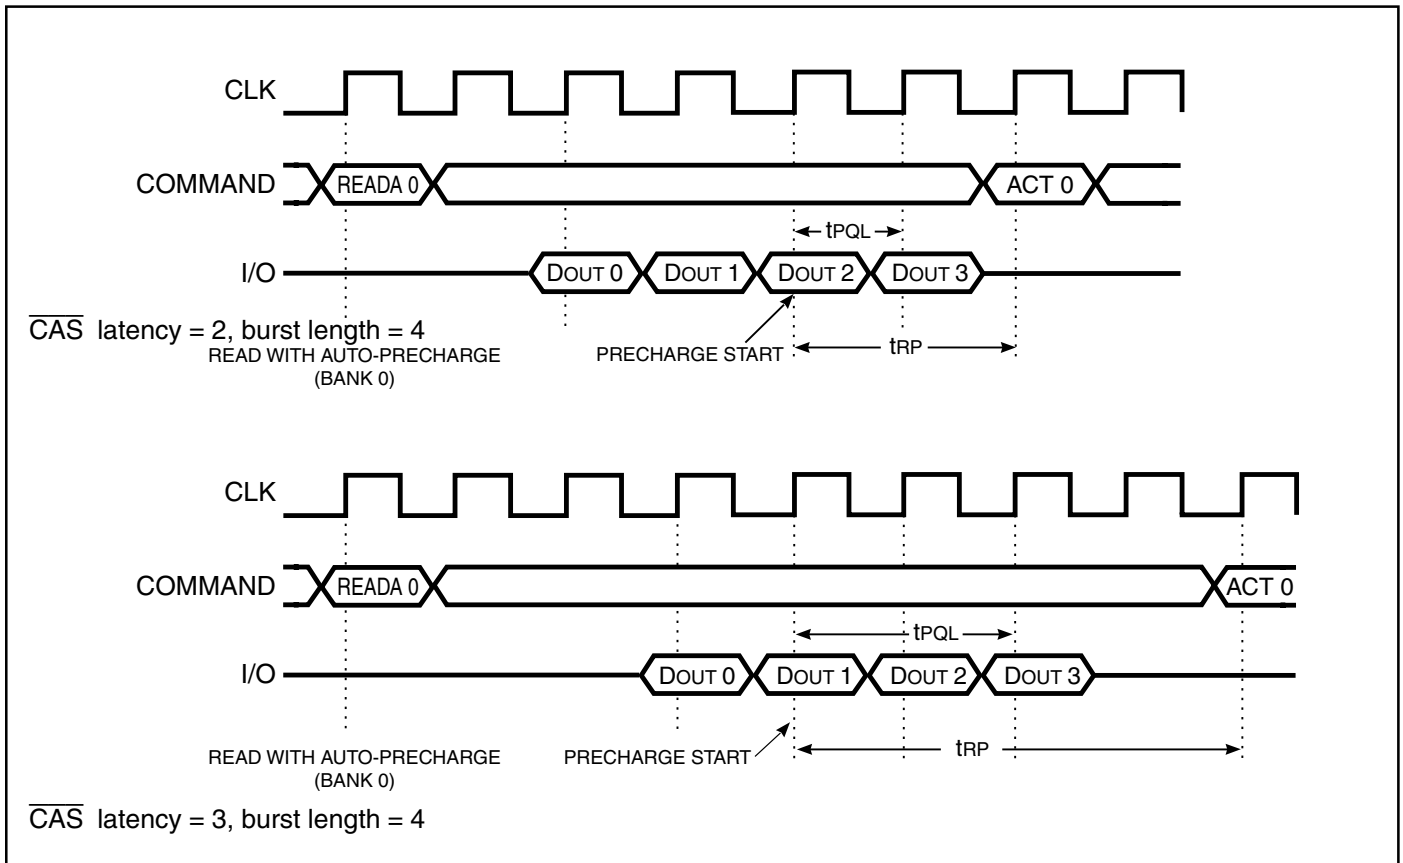

When the  $\overline{\text{CAS}}$  latency setting is one, the precharge operation starts at the same time as the last burst data is output ( $t_{PQL} = 0$ ). When the  $\overline{\text{CAS}}$  latency setting is two,

the precharge operation starts on one clock cycle before the last burst data is output ( $t_{PQL} = -1$ ). When the  $\overline{\text{CAS}}$  latency setting is three, the precharge operation starts on two clock cycles before the last burst data is output ( $t_{PQL} = -2$ ). Therefore, the selected bank can be made active after a delay of  $t_{RP}$  from the start position of this precharge operation.

The selected bank must be set to the active state before executing this command.

The auto-precharge function is invalid if the burst length is set to full page.

$\overline{\text{CAS}}$ Latency	3	2
$t_{PQL}$	-2	-1

**Write With Auto-Precharge**

The write with auto-precharge command first executes a burst write operation and then puts the selected bank in the precharged state automatically. After the precharge completes the bank goes to the idle state. Thus this command performs a write command and a precharge command in a single operation.

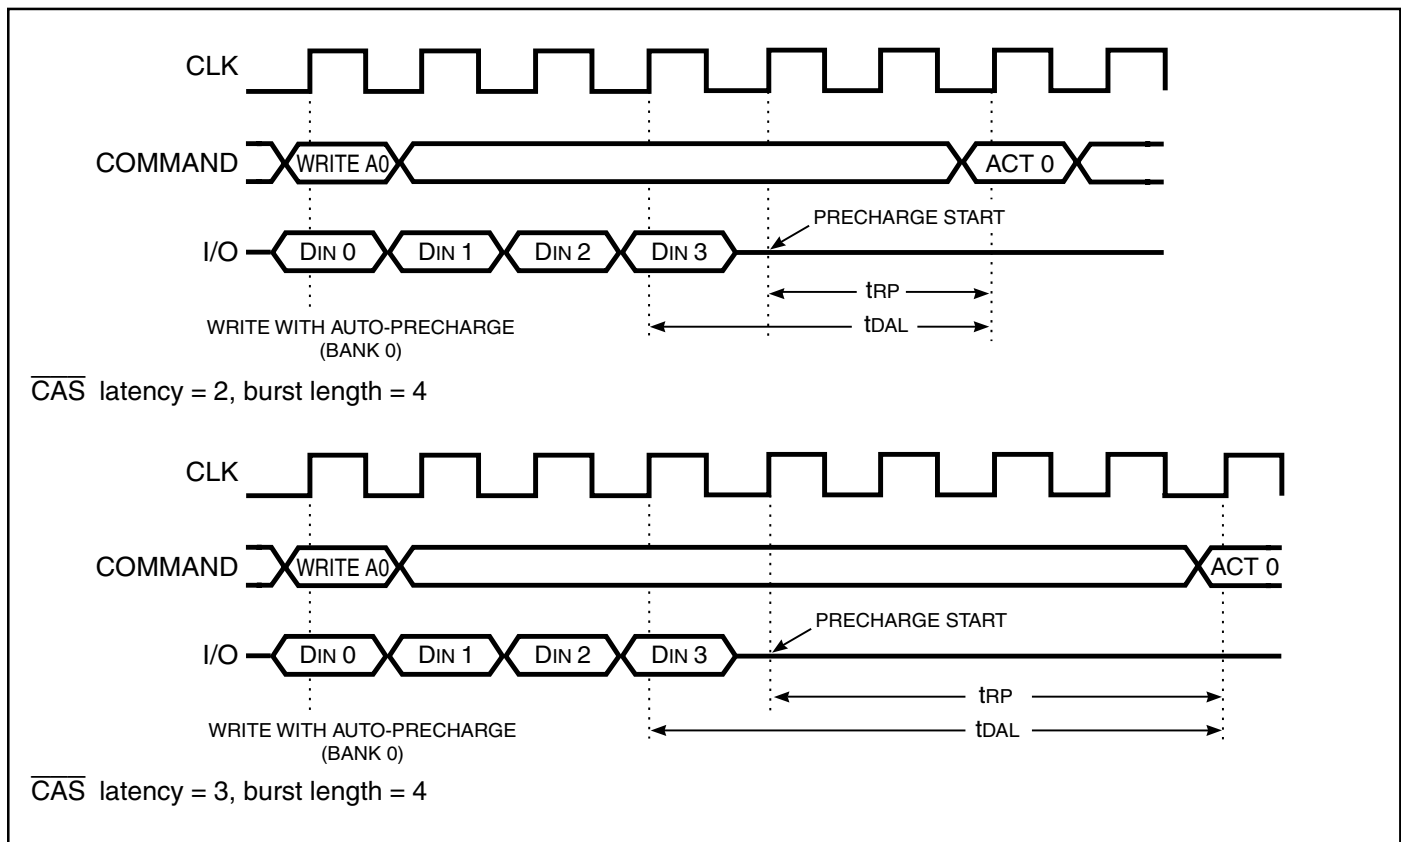

During this operation, the delay period ( $t_{DAL}$ ) between the last burst data input and the completion of the precharge operation differs depending on the  $\overline{CAS}$  latency setting. The delay ( $t_{DAL}$ ) is  $t_{RP}$  plus one CLK period. That is, the precharge operation starts one clock period after the last burst data input.

Therefore, the selected bank can be made active after a delay of  $t_{DAL}$ .

The selected bank must be set to the active state before executing this command.

The auto-precharge function is invalid if the burst length is set to full page.

$\overline{CAS}$ Latency	3	2
$t_{DAL}$	1CLK + $t_{RP}$	1CLK + $t_{RP}$

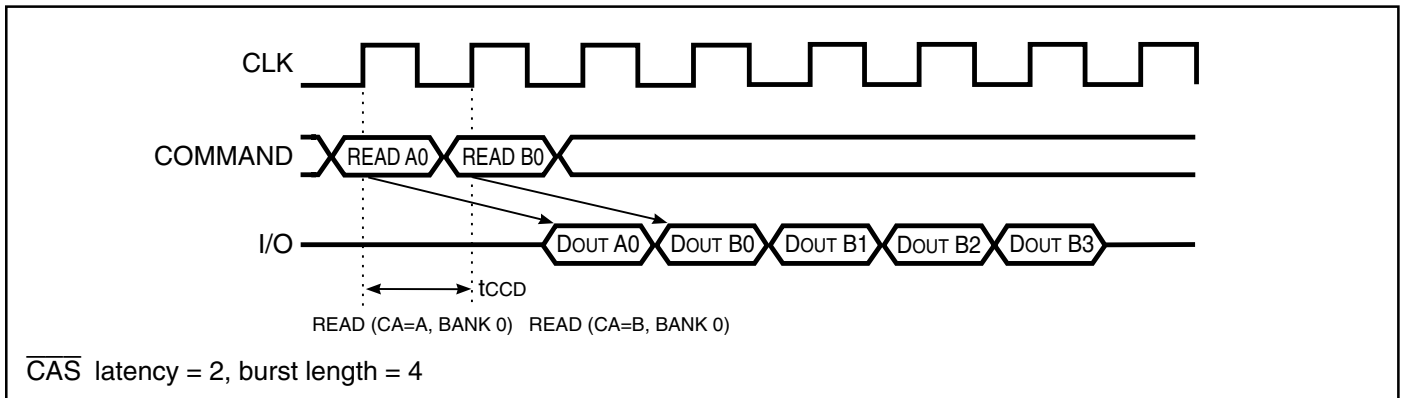

### Interval Between Read Command

A new command can be executed while a read cycle is in progress, i.e., before that cycle completes. When the second read command is executed, after the  $\overline{\text{CAS}}$  latency has elapsed, data corresponding to the new read command is output in place of the data due to the previous read command.

The interval between two read command ( $t_{\text{CCD}}$ ) must be at least one clock cycle.

The selected bank must be set to the active state before executing this command.

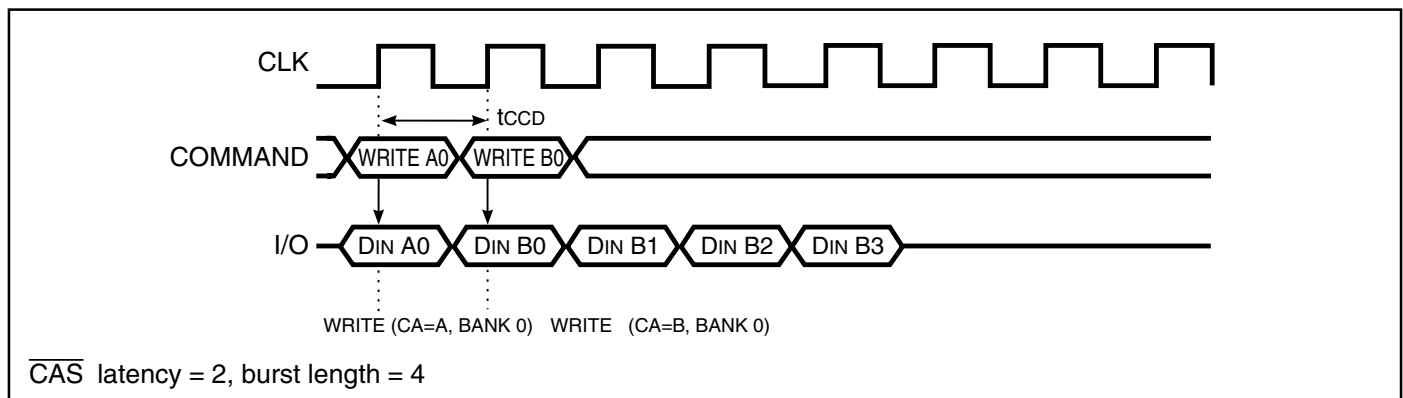

### Interval Between Write Command

A new command can be executed while a write cycle is in progress, i.e., before that cycle completes. At the point the second write command is executed, data corresponding to the new write command can be input in place of the data for the previous write command.

The interval between two write commands ( $t_{\text{CCD}}$ ) must be at least one clock cycle.

The selected bank must be set to the active state before executing this command.

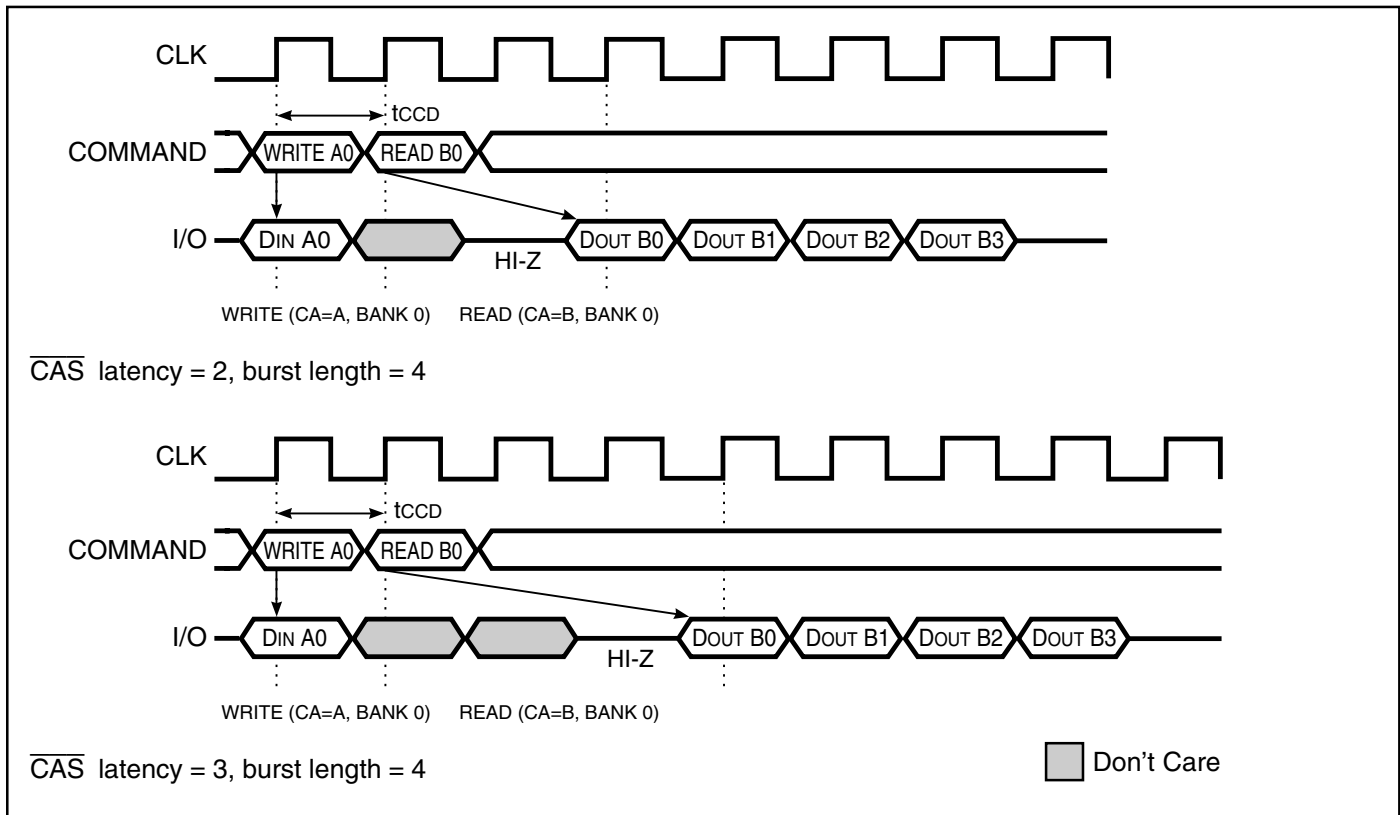

**Interval Between Write and Read Commands**

A new read command can be executed while a write cycle is in progress, i.e., before that cycle completes. Data corresponding to the new read command is output after the CAS latency has elapsed from the point the new read command was executed. The I/O pins must be placed in the HIGH impedance state at least one cycle before data is output during this operation.

The interval ( $t_{CCD}$ ) between command must be at least one clock cycle.

The selected bank must be set to the active state before executing this command.

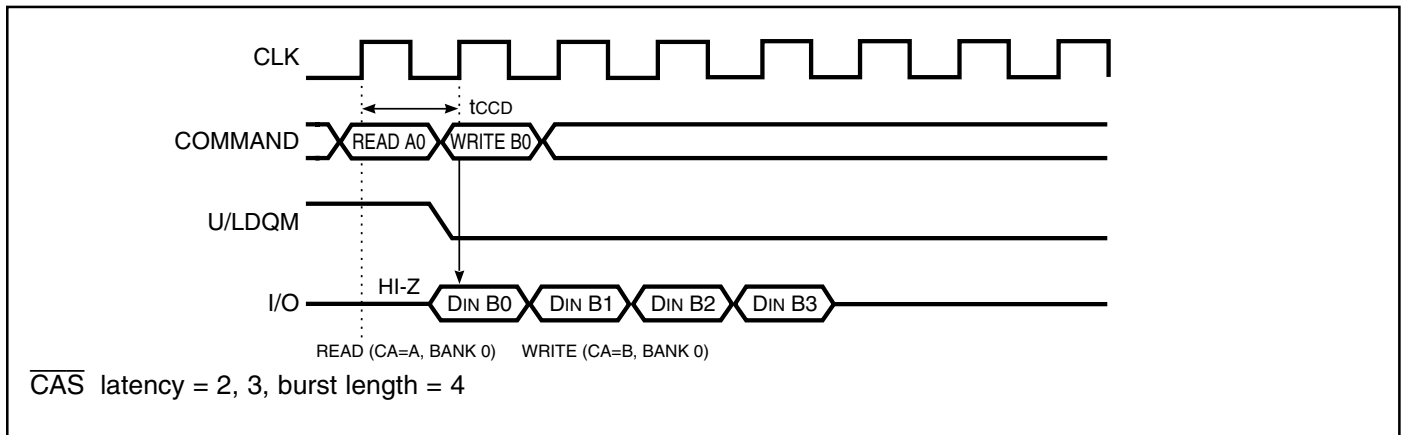

### Interval Between Read and Write Commands

A read command can be interrupted and a new write command executed while the read cycle is in progress, i.e., before that cycle completes. Data corresponding to the new write command can be input at the point new write command is executed. To prevent collision between input and output data at the I/O pins during this operation, the

output data must be masked using the U/LDQM pins. The interval ( $t_{CCD}$ ) between these commands must be at least one clock cycle.

The selected bank must be set to the active state before executing this command.

### Precharge

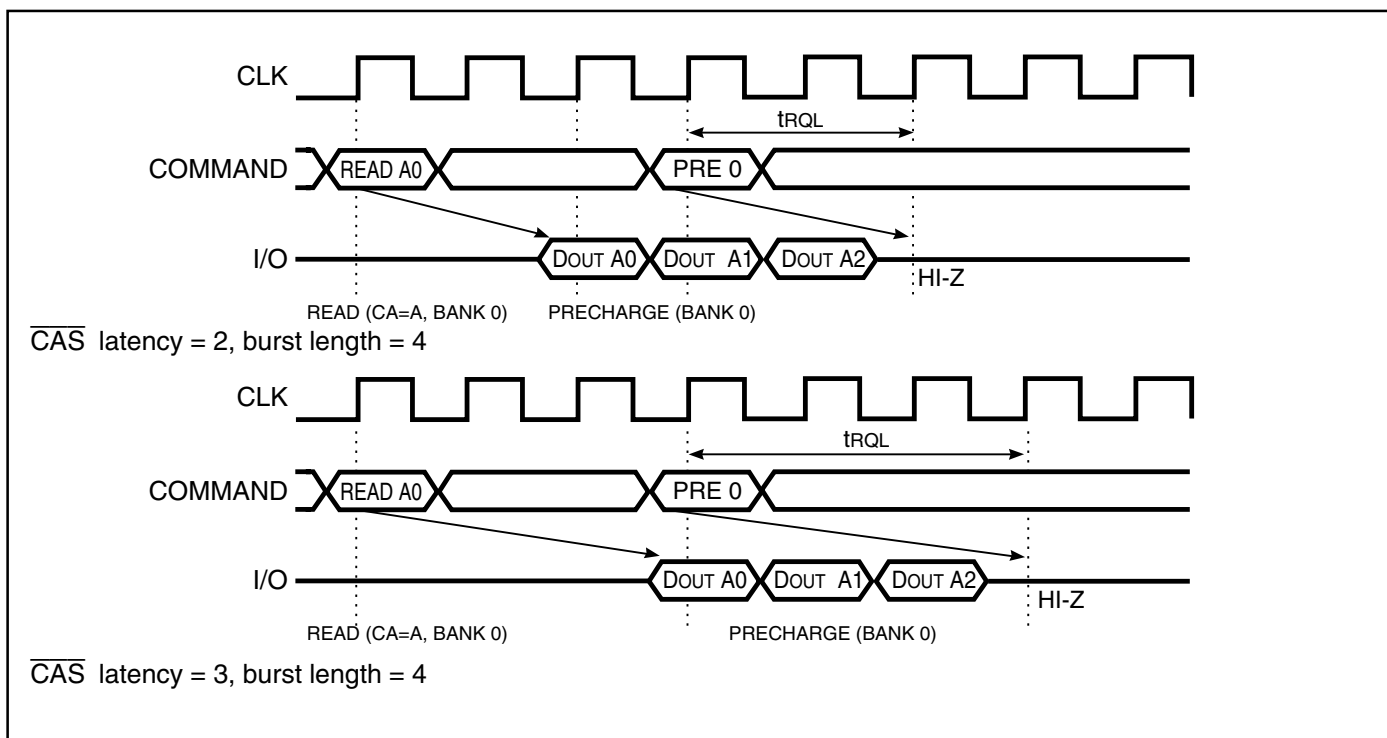

The precharge command sets the bank selected by pin A9 to the precharged state. This command can be executed at a time  $t_{RAS}$  following the execution of an active command to the same bank. The selected bank goes to the idle state at a time  $t_{RP}$  following the execution of the precharge command, and an active command can be executed again for that bank.

If pin A8 is low when this command is executed, the bank selected by pin A9 will be precharged, and if pin A8 is HIGH, both banks will be precharged at the same time. This input to pin A9 is ignored in the latter case.

### Read Cycle Interruption Using the Precharge Command

A read cycle can be interrupted by the execution of the precharge command before that cycle completes. The delay time ( $t_{RQL}$ ) from the execution of the precharge command to the completion of the burst output is the clock cycle of  $\overline{CAS}$  latency.

$\overline{CAS}$ Latency	3	2
$t_{RQL}$	3	2

### Write Cycle Interruption Using the Precharge Command

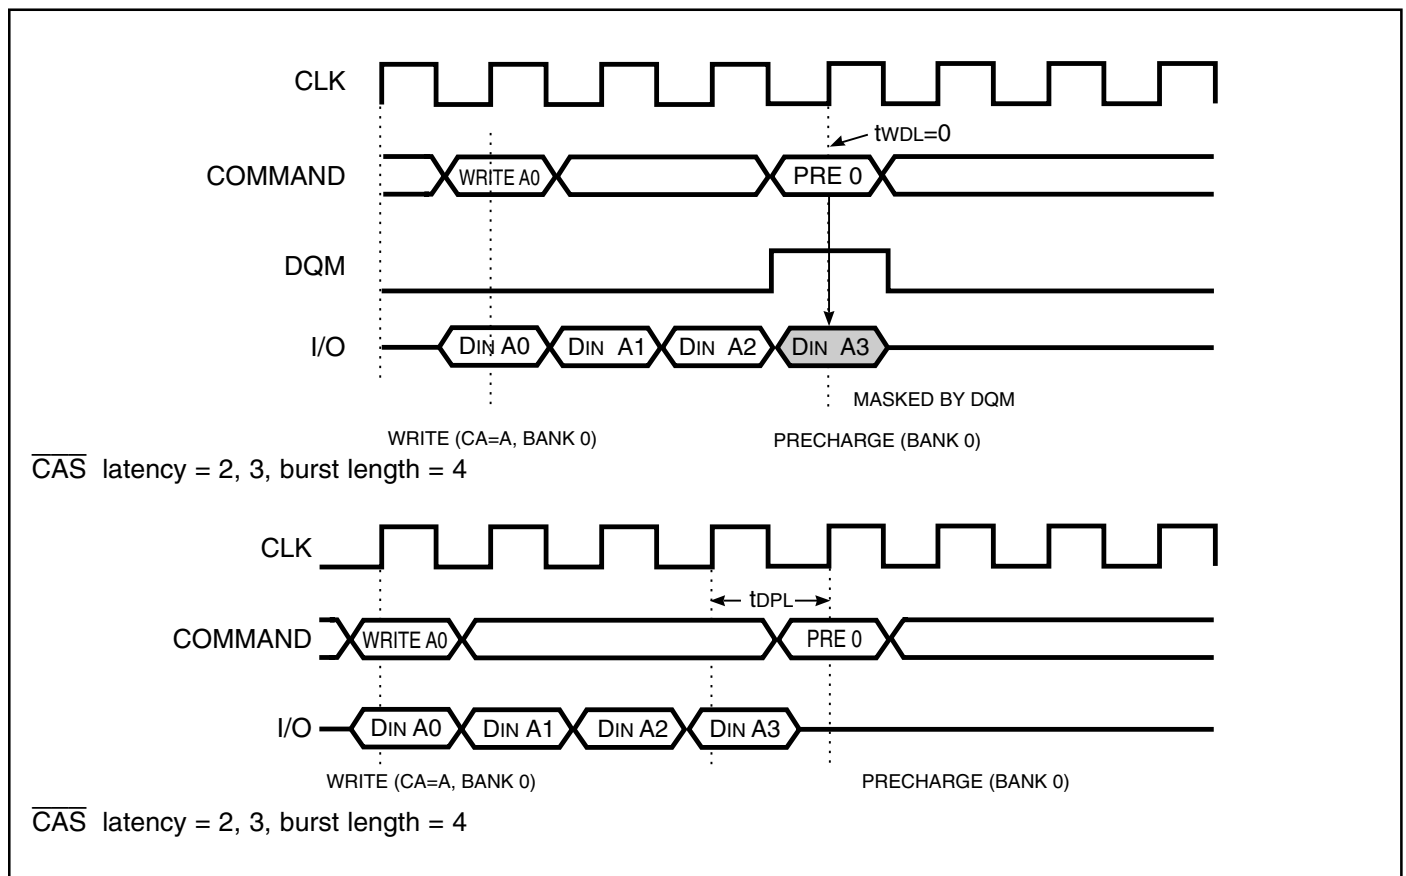

A write cycle can be interrupted by the execution of the precharge command before that cycle completes. The delay time ( $t_{WDL}$ ) from the precharge command to the point where burst input is invalid, i.e., the point where input data is no longer written to device internal memory is zero clock cycles regardless of the  $\overline{CAS}$ .

To inhibit invalid write, the DQM signal must be asserted HIGH with the precharge command.

This precharge command and burst write command must be of the same bank, otherwise it is not precharge interrupt but only another bank precharge of dual bank operation.

Inversely, to write all the burst data to the device, the precharge command must be executed after the write data recovery period ( $t_{DPL}$ ) has elapsed. Therefore, the precharge command must be executed on one clock cycle that follows the input of the last burst data item.

$\overline{CAS}$ Latency	3	2
$t_{WDL}$	0	0
$t_{DPL}$	1	1

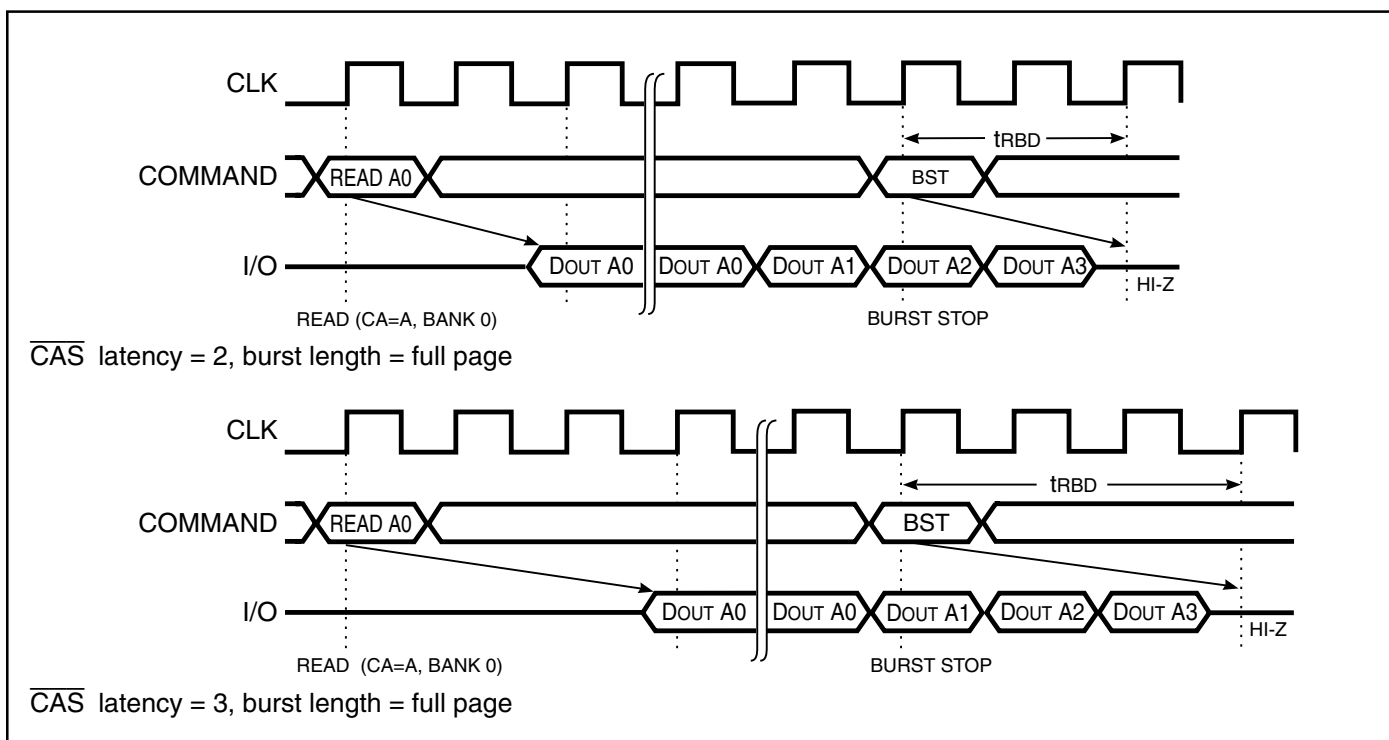

### Read Cycle (Full Page) Interruption Using the Burst Stop Command

The IS42S16128 can output data continuously from the burst start address (a) to location a+255 during a read cycle in which the burst length is set to full page. The IS42S16128 repeats the operation starting at the 256th cycle with the data output returning to location (a) and continuing with a+1, a+2, a+3, etc. A burst stop command must be executed to terminate this cycle. A precharge command must be executed within the ACT to PRE command period ( $t_{RAS\ max.}$ ) following the burst stop command.

After the period ( $t_{RBD}$ ) required for burst data output to stop following the execution of the burst stop command has elapsed, the outputs go to the HIGH impedance state. This period ( $t_{RBD}$ ) is one clock cycle when the  $\overline{CAS}$  latency is one, two clock cycle when the  $\overline{CAS}$  latency is two and three clock cycle when the CAS latency is three.

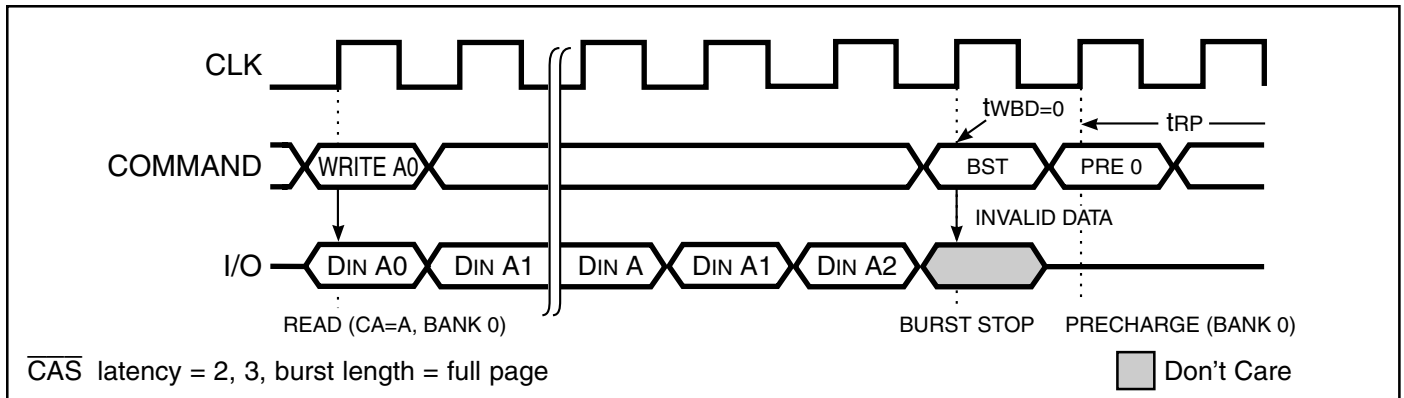

$\overline{CAS}$ Latency	3	2
$t_{RBD}$	3	2

### Write Cycle (Full Page) Interruption Using the Burst Stop Command

The IS42S16128 can input data continuously from the burst start address (a) to location a+255 during a write cycle in which the burst length is set to full page. The IS42S16128 repeats the operation starting at the 256th cycle with data input returning to location (a) and continuing with a+1, a+2, a+3, etc. A burst stop command must

be executed to terminate this cycle. A precharge command must be executed within the ACT to PRE command period ( $t_{RAS\ max.}$ ) following the burst stop command. After the period ( $t_{WBD}$ ) required for burst data input to stop following the execution of the burst stop command has elapsed, the write cycle terminates. This period ( $t_{WBD}$ ) is zero clock cycles, regardless of the  $\overline{CAS}$  latency.

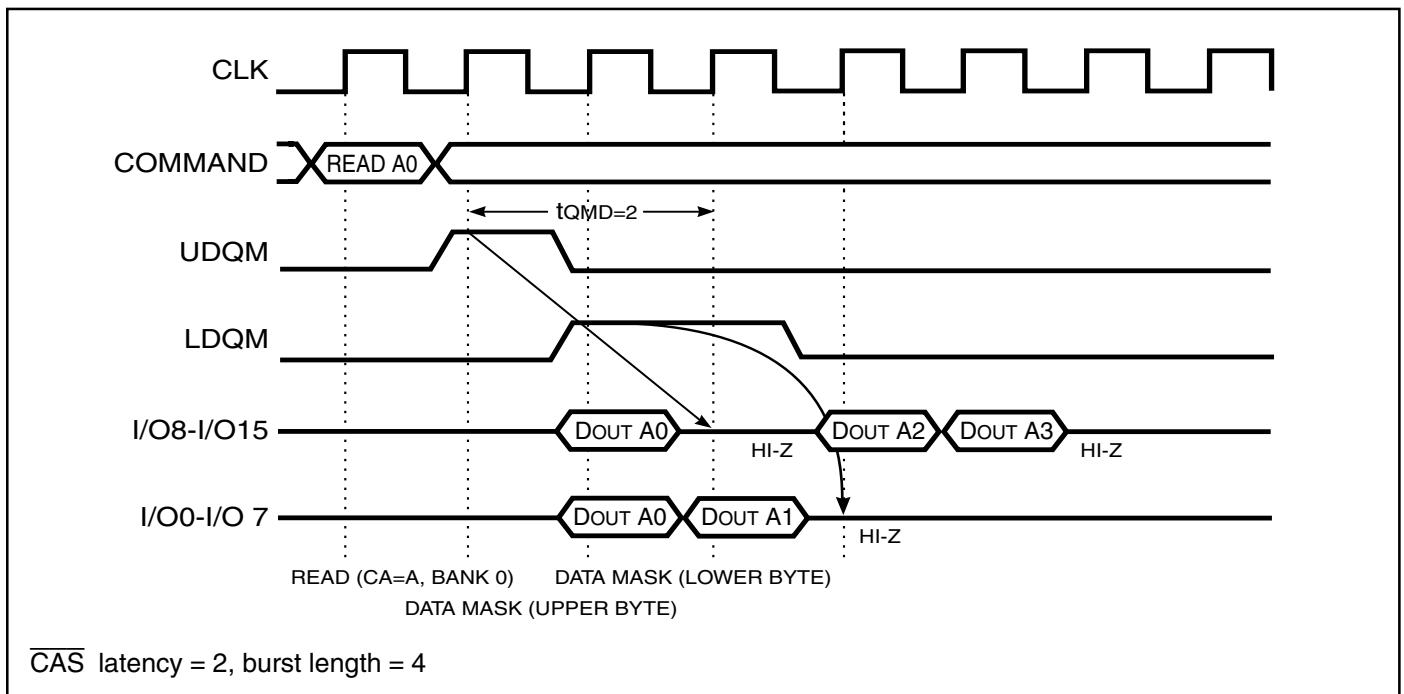

### Burst Data Interruption Using the U/LDQM Pins (Read Cycle)

Burst data output can be temporarily interrupted (masked) during a read cycle using the U/LDQM pins. Regardless of the  $\overline{CAS}$  latency, two clock cycles ( $t_{QMD}$ ) after one of the U/LDQM pins goes HIGH, the corresponding outputs go to the HIGH impedance state. Subsequently, the outputs are maintained in the high impedance state as long as

that U/LDQM pin remains HIGH. When the U/LDQM pin goes LOW, output is resumed at a time  $t_{QMD}$  later. This output control operates independently on a byte basis with the UDQM pin controlling upper byte output (pins I/O8-I/O15) and the LDQM pin controlling lower byte output (pins I/O0 to I/O7).

Since the U/LDQM pins control the device output buffers only, the read cycle continues internally and, in particular, incrementing of the internal burst counter continues.

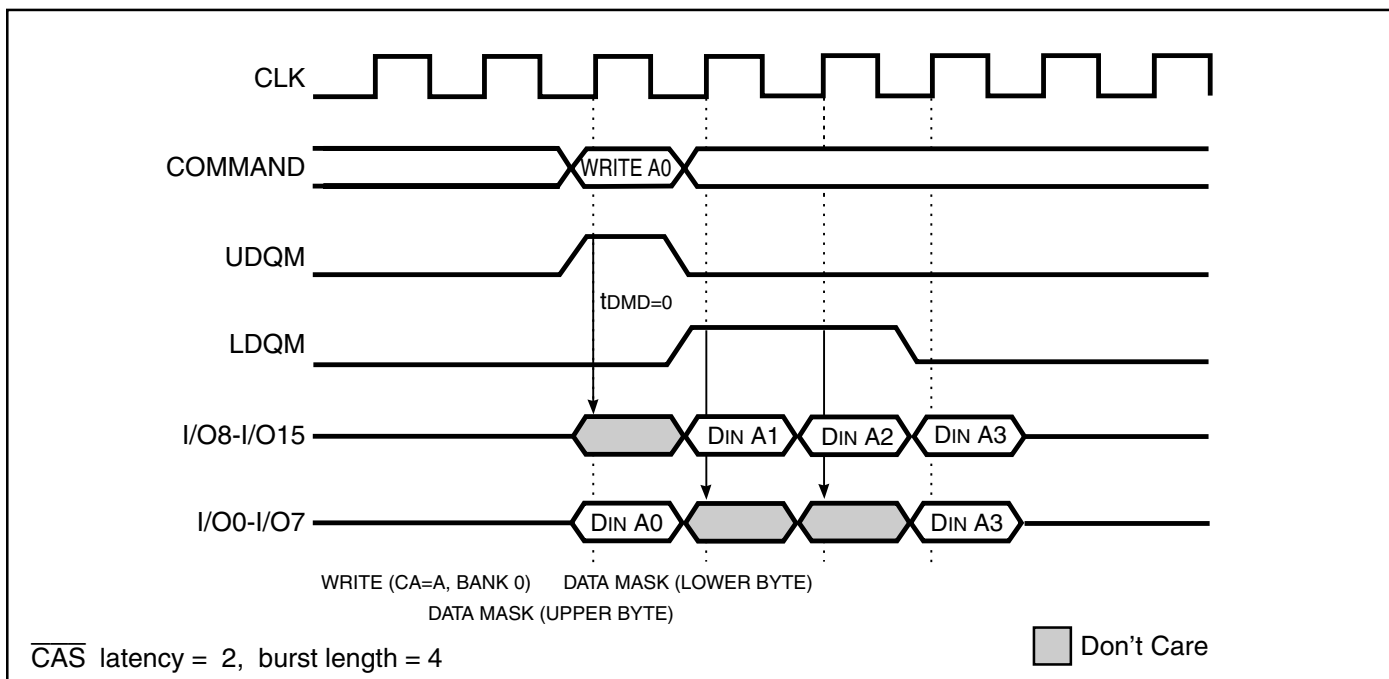

**Burst Data Interruption U/LDQM Pins (Write Cycle)**

Burst data input can be temporarily interrupted (muted) during a write cycle using the U/LDQM pins. Regardless of the CAS latency, as soon as one of the U/LDQM pins goes HIGH, the corresponding externally applied input data will no longer be written to the device internal circuits. Subsequently, the corresponding input continues to be muted as long as that U/LDQM pin remains HIGH.

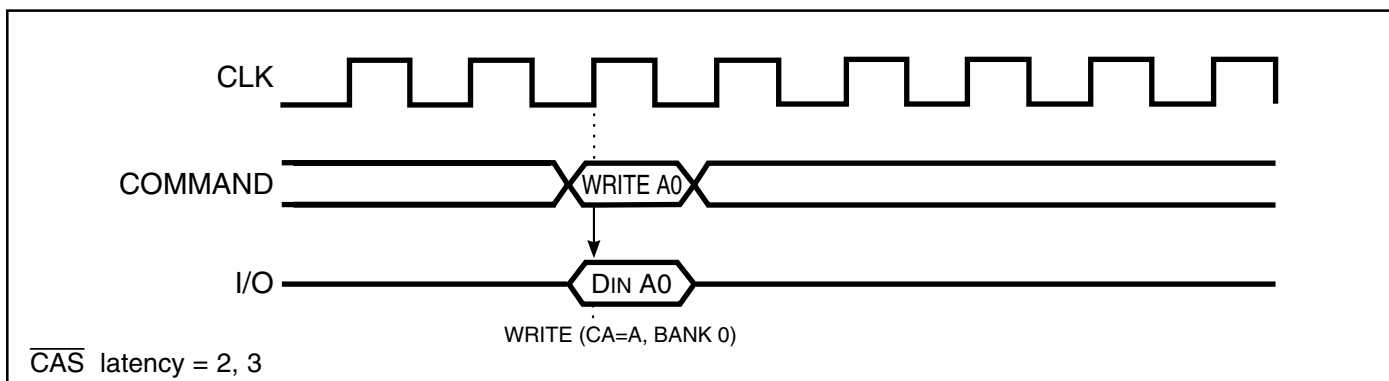

The IS42S16128 will revert to accepting input as soon as that pin is dropped to LOW and data will be written to the device. This input control operates independently on a byte basis with the UDQM pin controlling upper byte input (pin I/O8 to I/O15) and the LDQM pin controlling the lower byte input (pins I/O0 to I/O7).

Since the U/LDQM pins control the device input buffers only, the cycle continues internally and, in particular, incrementing of the internal burst counter continues.

**Burst Read and Single Write**

The burst read and single write mode is set up using the mode register set command. During this operation, the burst read cycle operates normally, but the write cycle only writes a single data item for each write cycle. The CAS latency and DQM latency are the same as in normal mode.

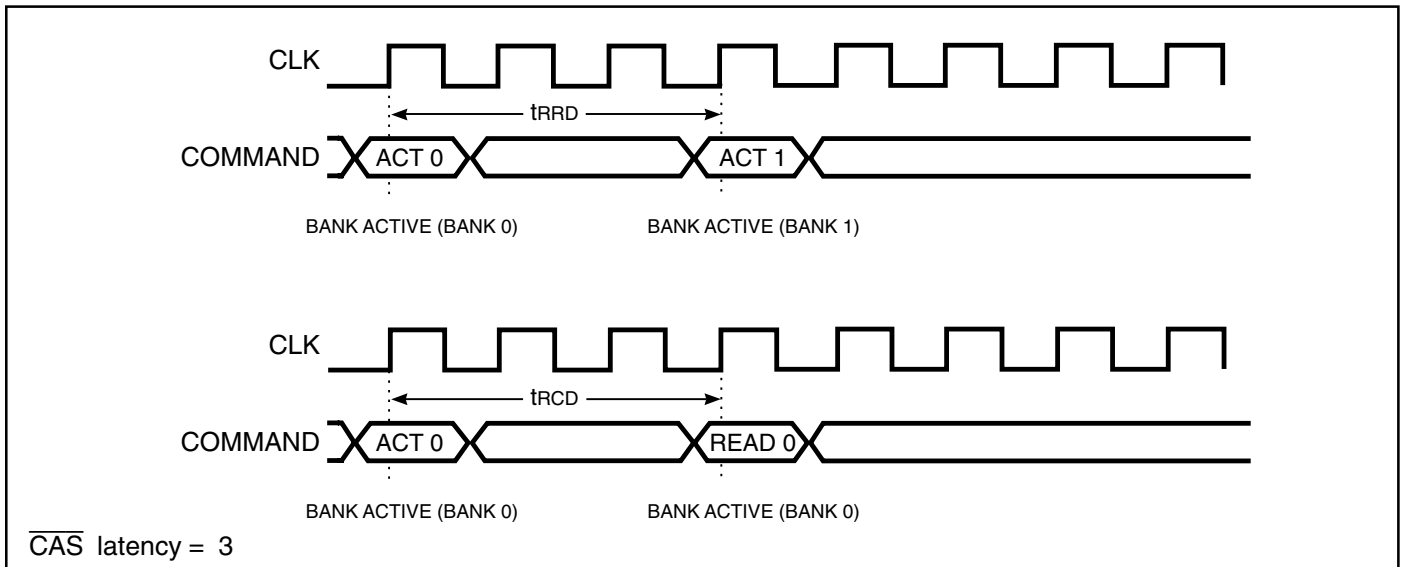

**Bank Active Command Interval**

When the selected bank is precharged, the period  $t_{RP}$  has elapsed and the bank has entered the idle state, the bank can be activated by executing the active command. If the other bank is in the idle state at that time, the active command can be executed for that bank after the period  $t_{RRD}$  has elapsed. At that point both banks will be in the active state. When a bank active command has been

executed, a precharge command must be executed for that bank within the ACT to PRE command period ( $t_{RAS}$  max.). Also note that a precharge command cannot be executed for an active bank before  $t_{RAS}$  (min.) has elapsed.

After a bank active command has been executed and the  $t_{RCD}$  period has elapsed, read/write (including auto-precharge) commands can be executed for that bank.

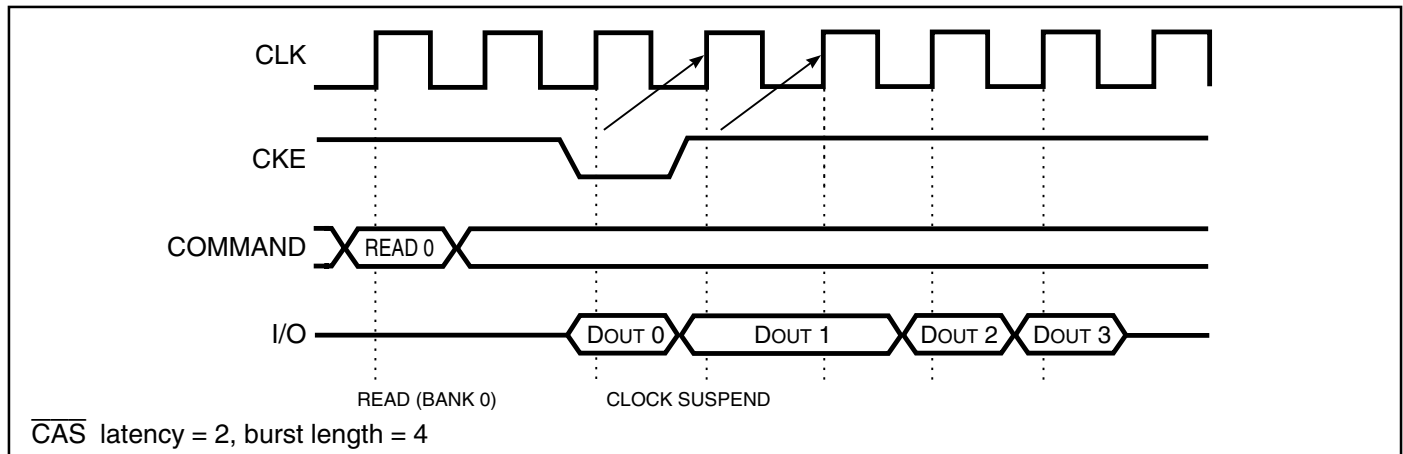

**Clock Suspend**

When the CKE pin is dropped from HIGH to LOW during a read or write cycle, the IS42S16128 enters clock suspend mode on the next CLK rising edge. This command reduces the device power dissipation by stopping the device internal clock. Clock suspend mode continues as long as the CKE pin remains low. In this state, all inputs other than CKE pin are invalid and no other commands can be executed. Also, the device internal states are maintained. When the CKE pin goes from LOW to HIGH,

clock suspend mode is terminated on the next CLK rising edge and device operation resumes.

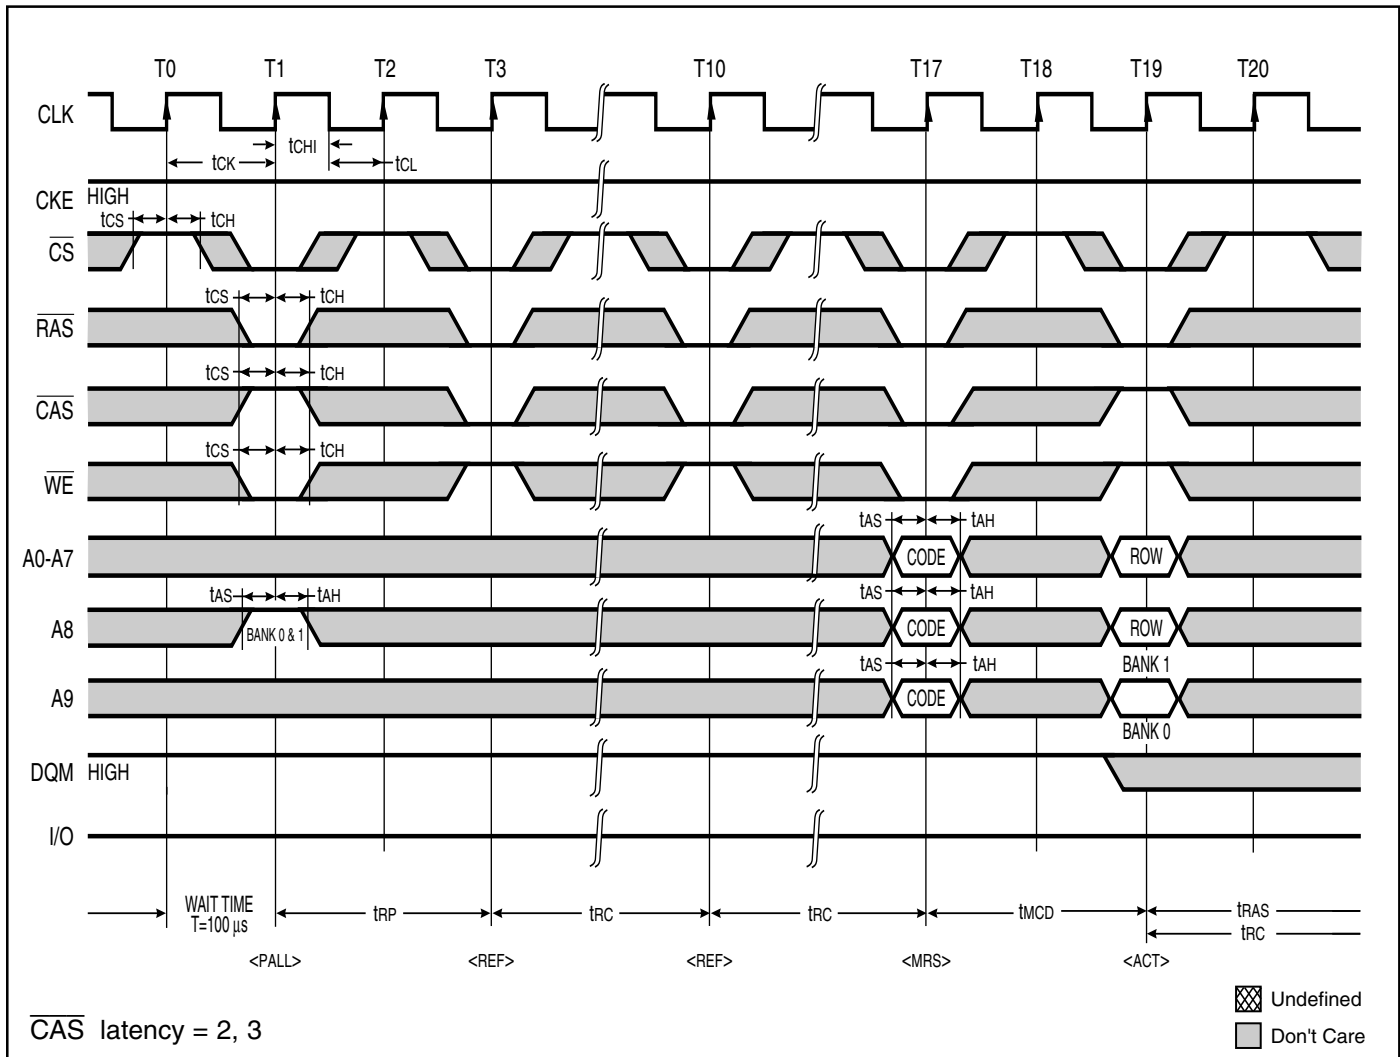

The next command cannot be executed until the recovery period ( $t_{CKA}$ ) has elapsed.

Since this command differs from the self-refresh command described previously in that the refresh operation is not performed automatically internally, the refresh operation must be performed within the refresh period ( $t_{REF}$ ). Thus the maximum time that clock suspend mode can be held is just under the refresh cycle time.
