### DESCRIPTION

The L6268 integrates into a single chip both spindle and VCM controllers as well as power stages. The device is designed for 12V disk drive application requiring up to 2.0A of spindle and 1.5A of VCM peak currents.

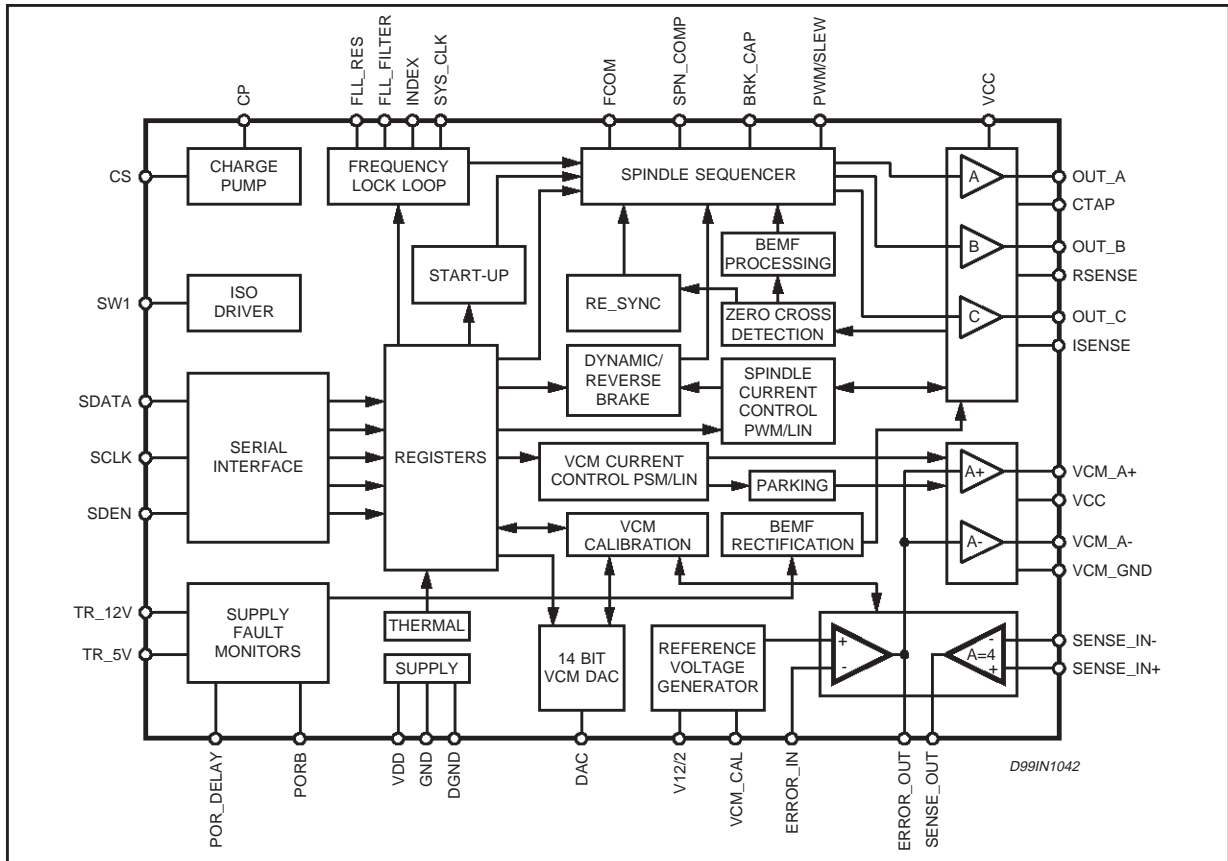

A serial port with up to 25 MHz capability provides easy interface to the microprocessor. A register controlled Frequency Locked Loop (FLL) allows flexibility in setting the spindle speed. Integrated BEMF processing, digital masking, digital delay, and sequencing minimize the number of external components required.

Power On Reset (POR) circuitry is included. Upon detection of a low voltage condition, POR is asserted, the internal registers are reset, and spindle power circuitry is tri-stated. The BEMF is rectified providing power for actuator retraction followed by dynamic spindle braking.

The device is built in BICMOS technology allowing dense digital/analog circuitry to be combined with a high power DMOS output stage.

## SERIAL PORT OPERATION

The serial port interface is a bi-directional port for reading and writing programming data from/to the internal registers of this device. For data transfers SDEN\* is brought high, serial data is presented at the SDATA pin, and a serial clock is applied to the SCLK pin. After the SDEN\* goes high, the first 16 pulses applied to the SCLK pin will shift the data presented at the SDATA pin into an internal shift register on the rising edge of each clock. An internal counter prevents more than 16 bits from being shifted into the register. The data in the shift register is latched after the 16th SCLK pulse. If less than 16 clock pulses are provided before SDEN\* goes low, the data transfer is aborted.

All transfers are shifted into the serial port LSB first. The first byte of the transfer is for R/W and address and instruction information. The first bit is R/W instruction bit, 0 is for WRITE and 1 is for READ. Following 7 bits are Address.
