LMH6739 Very Wideband, Low Distortion Triple Video Buffer

General Description

The LMH6739 is a very wideband, DC coupled monolithic programmable gain buffer designed specifically for ultra high resolution video systems as well as wide dynamic range systems requiring exceptional signal fidelity. Benefiting from National's current feedback architecture, the LMH6739 offers gains of -1, 1 and 2. At a gain of +2 the LMH6739 supports ultra high resolution video systems with a 400 MHz 2 V_{PP} 3 dB Bandwidth. With 12-bit distortion level through 30 MHz (R₁ = 100 Ω), 2.3nV/ \sqrt{Hz} input referred noise, the LMH6739 is the ideal driver or buffer for high speed flash A/D and D/A converters. Wide dynamic range systems such as radar and communication receivers requiring a wideband amplifier offering exceptional signal purity will find the LMH6739's low input referred noise and low harmonic distortion make it an attractive solution. The LMH6739 is available in a space saving SSOP package.

Features

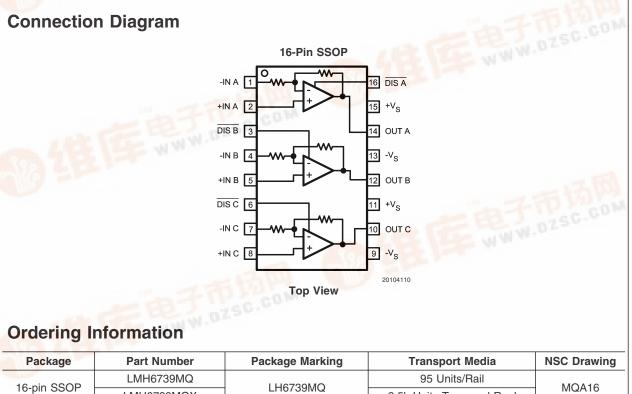

- 750 MHz –3 dB small signal bandwidth (A_V = +1)
- -85 dBc 3rd harmonic distortion (20 MHz)
- 2.3 nV/ √Hz input noise voltage
- 3300 V/µs slew rate
- 32 mA supply current (10.6 mA per op amp)
- 90 mA linear output current
- 0.02/0.01 Diff. Gain / Diff. Phase (R_L = 150Ω)

2.5k Units Tape and Reel

2mA shutdown current

Applications

- RGB video driver
 - High resolution projectors
 - Flash A/D driver
 - D/A transimpedance buffer
 - Wide dynamic range IF amp
 - Radar/communication receivers
 - DDS post-amps
 - Wideband inverting summer
- Line driver

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications, see the Electrical Characteristics tables.

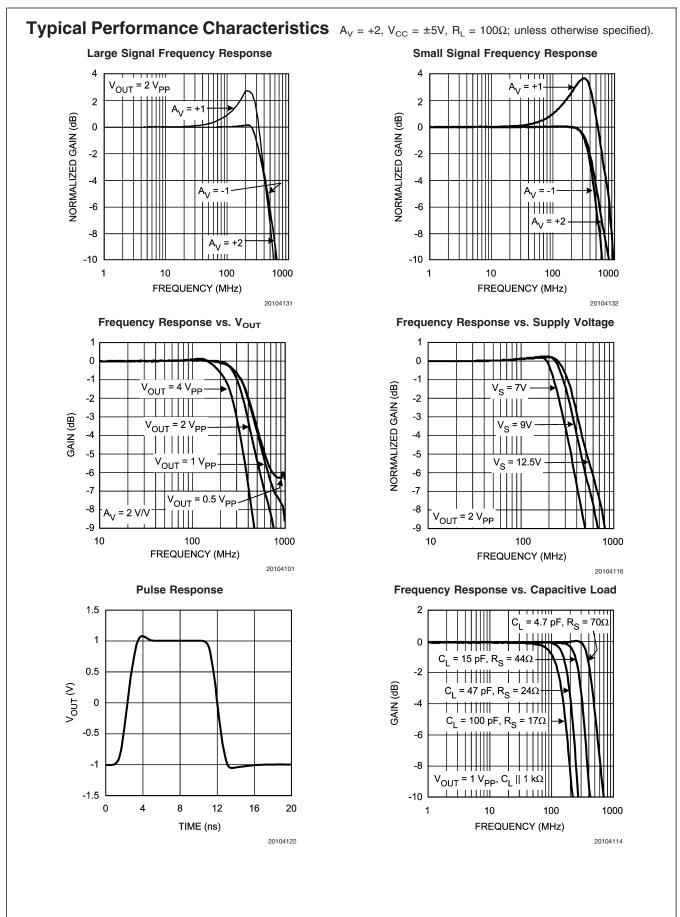

Note 2: Electrical Table values apply only for factory testing conditions at the temperature indicated. Factory testing conditions result in very limited self-heating of the device such that $T_J = T_A$. No guarantee of parametric performance is indicated in the electrical tables under conditions of internal self heating where $T_J > T_A$. See Applications Section for information on temperature de-rating of this device. Min/Max ratings are based on product characterization and simulation. Individual parameters are tested as noted.

Note 3: The maximum output current (I_{OUT}) is determined by device power dissipation limitations. See the Power Dissipation section of the Application Section for more details.

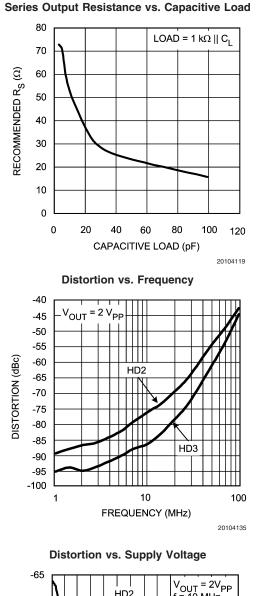

Note 4: Human body model: 1.5 k Ω in series with 100 pF. Machine model: 0Ω in series with 200 pF.

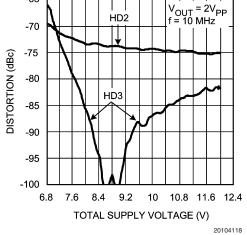

Note 5: Short circuit current should be limited in duration to no more than 10 seconds. See the Power Dissipation section of the Application Section for more details. Note 6: Parameter 100% production tested at 25° C.

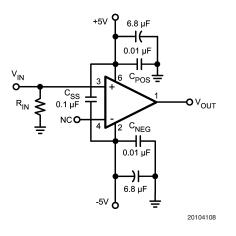

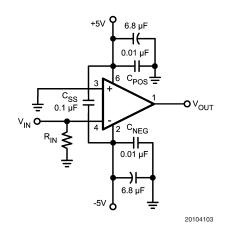

FIGURE 2. Recommended Non-Inverting Gain Circuit, Gain +1

GENERAL INFORMATION

The LMH6739 is a high speed current feedback Programmable Gain Buffer (PGB), optimized for very high speed and low distortion. With its internal feedback and gain-setting resistors the LMH6739 offers excellent AC performance while simplifying board layout and minimizing the affects of layout related parasitic components. The LMH6739 has no internal ground reference so single or split supply configurations are both equally useful.

SETTING THE CLOSED LOOP GAIN

The LMH6739 is a current feedback amplifier with on-chip $R_F = R_G = 450\Omega$. As such it can be configured with an $A_V = +2$, $A_V = +1$, or an $A_V = -1$ by connecting pins 3 and 4 as described in the chart below.

GAIN A _v	INPUT CONNECTIONS		
	Non-Inverting (Pin 3)	Inverting (Pin 4)	
-1 V/V	Ground	Input Signal	
+1 V/V	Input Signal	NC (Open)	
+2 V/V	Input Signal	Ground	

The gain of the LMH6739 is accurate to ±1% and stable over temperature. The internal gain setting resistors, R_F and R_G, match very well. However, over process and temperature their absolute value will change. Using external resistors in series with R_G to change the gain will result in poor gain accuracy over temperature and from part to part.

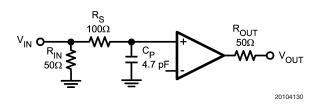

FIGURE 4. Correction for Unity Gain Peaking

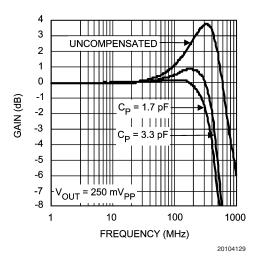

FIGURE 5. Frequency Response for Circuit in Figure 4

Application Section (Continued)

UNITY GAIN COMPENSATION

With a current feedback PGB like the LMH6739, the feedback resistor is a compromise between the value needed for stability at unity gain and the optimized value used at a gain of two. The result of this compromise is substantial peaking at unity gain. If this peaking is undesirable a simple RC filter at the input of the buffer will smooth the frequency response shown as *Figure 4. Figure 5* shows the results of a simple filter placed on the non-inverting input. See *Figure 6* and *Figure 7* for another method for reducing unity gain peaking.

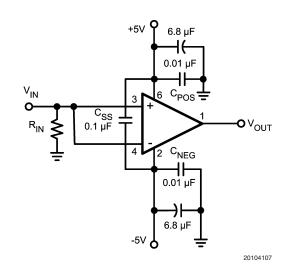

FIGURE 6. Alternate Unity Gain Compensation

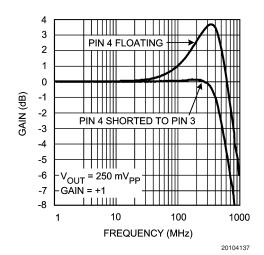

FIGURE 7. Frequency Response for Circuit in Figure 6

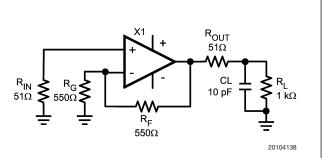

FIGURE 8. Decoupling Capacitive Loads

DRIVING CAPACITIVE LOADS

Capacitive output loading applications will benefit from the use of a series output resistor R_{OUT} . *Figure 8* shows the use of a series output resistor, R_{OUT} , to stabilize the amplifier output under capacitive loading. Capacitive loads of 5 to 120 pF are the most critical, causing ringing, frequency response peaking and possible oscillation. The charts "Suggested R_{OUT} vs. Cap Load" give a recommended value for selecting a series output resistor for mitigating capacitive loads. The values suggested in the charts are selected for .5 dB or less of peaking in the frequency response. This gives a good compromise between settling time and bandwidth. For applications where maximum frequency response is needed and some peaking is tolerable, the value of R_{OUT} can be reduced slightly from the recommended values.

LAYOUT CONSIDERATIONS

Whenever questions about layout arise, use the evaluation board as a guide. The LMH730275 is the evaluation board supplied with samples of the LMH6739.

To reduce parasitic capacitances ground and power planes should be removed near the input and output pins. Components in the feedback loop should be placed as close to the device as possible. For long signal paths controlled impedance lines should be used, along with impedance matching elements at both ends.

Bypass capacitors should be placed as close to the device as possible. Bypass capacitors from each rail to ground are applied in pairs. The larger electrolytic bypass capacitors can be located farther from the device, the smaller ceramic capacitors should be placed as close to the device as possible. The LMH6739 has multiple power and ground pins for enhanced supply bypassing. Every pin should ideally have a separate bypass capacitor. Sharing bypass capacitors may slightly degrade second order harmonic performance, especially if the supply traces are thin and /or long. In *Figure 1* and *Figure 2* C_{SS} is optional, but is recommended for best second harmonic distortion. Another option to using C_{SS} is to use pairs of .01 μ F and .1 μ F ceramic capacitors for each supply bypass.

VIDEO PERFORMANCE

The LMH6739 has been designed to provide excellent performance with production quality video signals in a wide variety of formats such as HDTV and High Resolution VGA. NTSC and PAL performance is nearly flawless. Best performance will be obtained with back terminated loads. The back termination reduces reflections from the transmission line and effectively masks transmission line and other parasitic capacitances from the amplifier output stage. *Figure 4*

Application Section (Continued)

shows a typical configuration for driving a 75Ω Cable. The amplifier is configured for a gain of two to make up for the 6 dB of loss in $R_{\rm OUT}.$

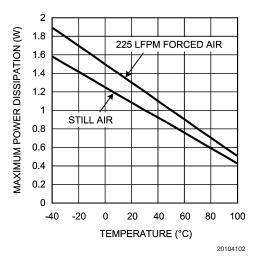

FIGURE 9. Maximum Power Dissipation

POWER DISSIPATION

The LMH6739 is optimized for maximum speed and performance in the small form factor of the standard SSOP-16 package. To achieve its high level of performance, the LMH6739 consumes an appreciable amount of quiescent current which cannot be neglected when considering the total package power dissipation limit. The quiescent current contributes to about 40° C rise in junction temperature when no additional heat sink is used ($V_S = \pm 5V$, all 3 channels on). Therefore, it is easy to see the need for proper precautions to be taken in order to make sure the junction temperature's absolute maximum rating of 150°C is not violated.

To ensure maximum output drive and highest performance, thermal shutdown is not provided. Therefore, it is of utmost importance to make sure that the T_{JMAX} is never exceeded due to the overall power dissipation (all 3 channels).

With the LMH6739 used in a back-terminated 75 Ω RGB analog video system (with 2 V_{PP} output voltage), the total power dissipation is around 435 mW of which 340 mW is due to the quiescent device dissipation (output black level at 0V). With no additional heat sink used, that puts the junction temperature to about 140° C when operated at 85°C ambient.

To reduce the junction temperature many options are available. Forced air cooling is the easiest option. An external

add-on heat-sink can be added to the SSOP-16 package, or alternatively, additional board metal (copper) area can be utilized as heat-sink.

An effective way to reduce the junction temperature for the SSOP-16 package (and other plastic packages) is to use the copper board area to conduct heat. With no enhancement the major heat flow path in this package is from the die through the metal lead frame (inside the package) and onto the surrounding copper through the interconnecting leads. Since high frequency performance requires limited metal near the device pins the best way to use board copper to remove heat is through the bottom of the package. A gap filler with high thermal conductivity can be used to conduct heat from the bottom of the package to copper on the circuit board. Vias to a ground or power plane on the back side of the circuit board will provide additional heat dissipation. A combination of front side copper and vias to the back side can be combined as well.

Follow these steps to determine the maximum power dissipation for the LMH6739:

- 1. Calculate the quiescent (no-load) power: $\mathsf{P}_{\mathsf{AMP}}$ = $\mathsf{I}_{\mathsf{CC}}^*$ $(\mathsf{V}_{\mathsf{S}})$ V_{S} = V^+-V^-
- 2. Calculate the RMS power dissipated in the output stage: P_D (rms) = rms ((V_S - V_{OUT})*I_{OUT}) where V_{OUT} and I_{OUT} are the voltage and current across the external load and V_S is the total supply current
- 3. Calculate the total RMS power: $P_T = P_{AMP} + P_D$

The maximum power that the LMH6739 package can dissipate at a given temperature can be derived with the following equation (See *Figure 9*):

 $\begin{array}{l} \mathsf{P}_{MAX} = (150^\circ - \mathsf{T}_{AMB}) / \left. \theta_{JA} \text{, where } \mathsf{T}_{AMB} = \text{Ambient temperature (°C) and } \theta_{JA} = \text{Thermal resistance, from junction to ambient, for a given package (°C/W). For the SSOP package } \theta_{JA} \text{ is } 120^\circ\text{C/W}. \end{array}$

ESD PROTECTION

The LMH6739 is protected against electrostatic discharge (ESD) on all pins. The LMH6739 will survive 2000V Human Body model and 200V Machine model events.

Under closed loop operation the ESD diodes have no effect on circuit performance. There are occasions, however, when the ESD diodes will be evident. If the LMH6739 is driven by a large signal while the device is powered down the ESD diodes will conduct.

The current that flows through the ESD diodes will either exit the chip through the supply pins or will flow through the device, hence it is possible to power up a chip with a large signal applied to the input pins. Shorting the power pins to each other will prevent the chip from being powered up through the input.
