FUNCTIONAL DESCRIPTIONS

The divide ratio can be calculated using the following equation:

$$f_{vco} = \{(P \times N) + A\} \times f_{osc} \div R \quad (A < N)$$

- f_{vco} : Output frequency of external voltage controlled oscillator (VCO)
- P: Preset divide ratio of dual modulus prescaler (16 or 32 for IF-PLL, 64 or 128 for RF-PLL)
- N: Preset divide ratio of binary 11-bit programmable counter (5 to 2,047)
- A: Preset divide ratio of binary 7-bit swallow counter ($0 \leq A \leq 127$)
- f_{osc} : Reference oscillation frequency
- R: Preset divide ratio of binary 14-bit programmable reference counter (5 to 16,383)

Serial Data Input

Serial data is entered using three pins, Data pin, Clock pin, and LE pin. Programmable dividers of IF/RF-PLL sections, programmable reference dividers of IF/RF PLL sections are controlled individually.

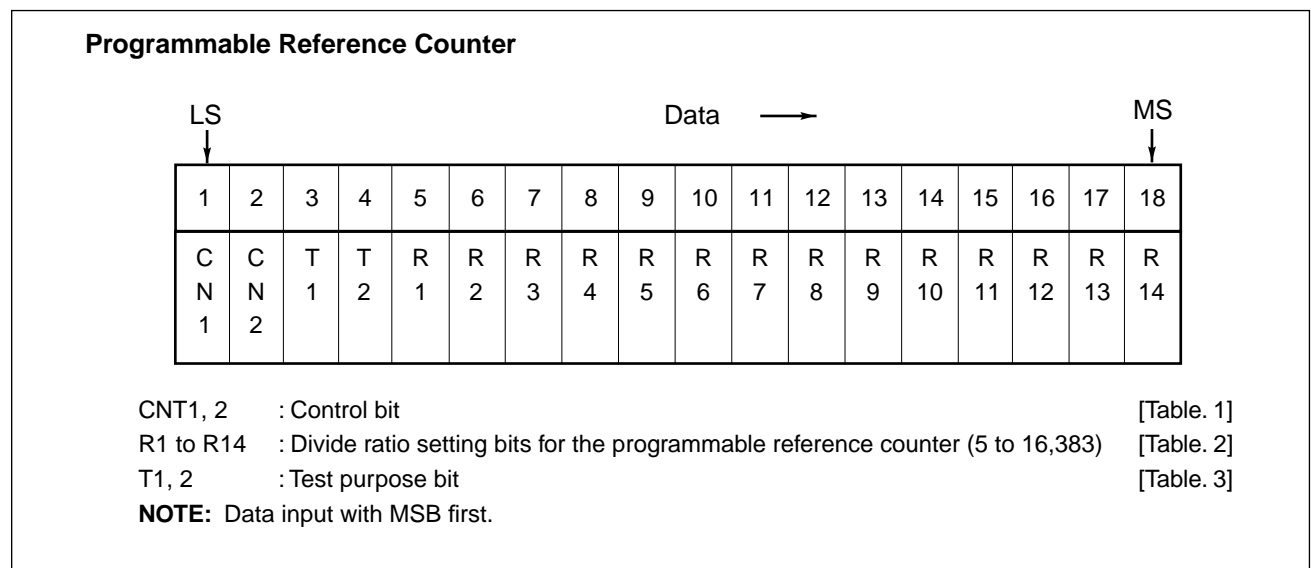

Serial data of binary data is entered through Data pin.

On rising edge of clock, one bit of serial data is transferred into the shift register. When load enable signal is high, the data stored in the shift register is transferred to one of latch of them depending upon the control bit data setting.

■ PHASE DETECTOR OUTPUT WAVEFORM

- Note:
- Phase error detection range = -2π to $+2\pi$
 - Pulses on $Do_{IF/RF}$ signals are output to prevent dead zone.
 - LD output becomes low when phase error is t_{wU} or more.
 - LD output becomes high when phase error is t_{wL} or less and continues to be so for three cycles or more.
 - t_{wU} and t_{wL} depend on OSC_{in} input frequency as follows.
 - $t_{wU} \geq 8/f_{osc}$: i.e. $t_{wU} \geq 625ns$ when $f_{osc} = 12.8 MHz$
 - $t_{wL} \leq 16/f_{osc}$: i.e. $t_{wL} \leq 1250ns$ when $f_{osc} = 12.8 MHz$

■ POWER SAVING MODE (INTERMITTENT MODE CONTROL CIRCUIT)

Setting a $PS_{IF(RF)}$ pin to Low, IF-PLL (RF-PLL) enters into power saving mode resultant current consumption can be limited to $10\mu A$ (typ.). Setting PS pin to High, power saving mode is released so that the device works normally. In addition, the intermittent operation control circuit is included which helps smooth start up from stand by mode. In general, the power consumption can be saved by the intermittent operation that powering down or waking up the synthesizer. Such case, if the PLL is powered up uncontrolled, the resulting phase comparator output signal is unpredictable due to an undefined phase relation between reference frequency (f_r) and comparison frequency (f_p) and may in the worst case take longer time for lock up of the loop.

To prevent this, the intermittent operation control circuit enforces a limited error signal output of the phase detector during power up. Thus keeping the loop locked.

PS pin must be set "L" at Power-ON.

Allow $1\ \mu s$ after frequency stabilization on power-up for exiting the power saving mode (PS: L to H)

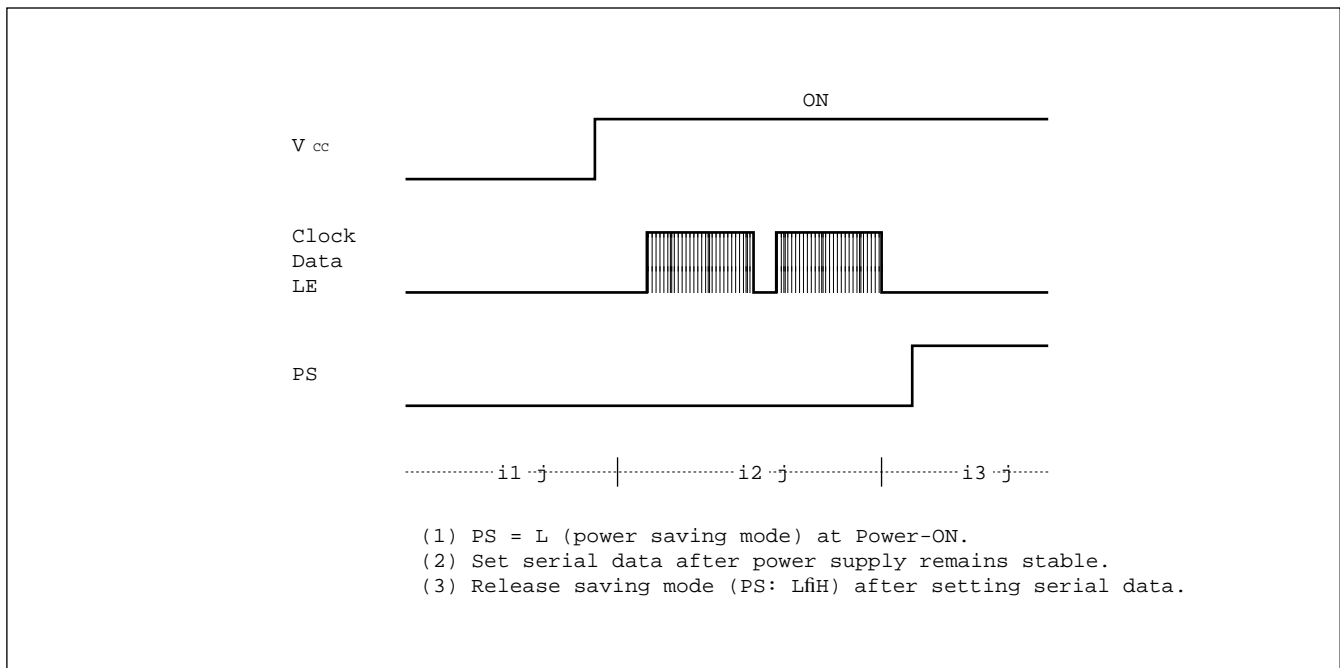

Serial data can be entered during the power saving mode.

During the power saving mode, the corresponding section except for indispensable circuit for the power saving function stops working, then current consumption is reduced to $10\mu A$ per one PLL section.

At that time, the Do and LD become the same state as when a loop is locking. That is, the Do becomes high impedance.

A VCO control voltage is naturally kept at the locking voltage which defined by a LPF's time constant. As a result of this, VCO's frequency is kept at the locking frequency.

L	L	OFF	OFF	OFF
H	L	ON	OFF	ON
L	H	OFF	ON	ON
H	H	ON	ON	ON
