

# Dual/Quad Single Supply Operational Amplifier

## OP292/OP492

### FEATURES

- Single Supply Operation: 4.5 V to 33 V
- Input Common Mode Includes Ground
- Output Swings to Ground
- High Slew Rate: 3 V/ $\mu$ s
- High Gain Bandwidth: 4 MHz
- Low Input Offset Voltage
- High Open-Loop Gain
- No Phase Inversion
- Low Cost

### APPLICATIONS

- Disk Drives
- Mobile Phones
- Servo Controls
- Modems and Fax Machines
- Pagers
- Power Supply Monitors and Controls
- Battery Operated Instrumentation

### GENERAL DESCRIPTION

The OP292/OP492 are low cost general purpose dual and quad operational amplifiers designed for single supply applications and are ideal for +5 volt systems.

Fabricated on Analog Devices' CBCMOS process, the OP292/OP492 series has a PNP input stage that allows the input voltage range to include ground. A BiCMOS output stage enables the output to swing to ground while sinking current.

The OP292/OP492 series is unity-gain stable and features an outstanding combination of speed and performance for single or dual supply operation. The OP292/OP492 provide high slew rate, high bandwidth, with open-loop gain exceeding 40,000 and offset voltage under 800  $\mu$ V (OP292) and 1 mV (OP492). With these combinations of features and low supply current, the OP292/OP492 series is an excellent choice for battery operated applications.

The OP292/OP492 series performance is specified for single or dual supply voltage operation over the extended industrial temperature range (-40°C to +125°C).

Package options for the OP292 and OP492 include plastic DIP, SO-8 (OP292) and SO-14.

### PIN CONNECTIONS

8-Lead Narrow-Body SO (S Suffix)

8-Lead Epoxy DIP (P Suffix)

14-Lead Narrow-Body SO (S Suffix)

14-Lead Epoxy DIP (P Suffix)

### NOTES

Electrical tests and wafer probe to the limits shown. Due to variations in assembly methods and normal yield loss, yield after packaging is not guaranteed for standard product dice. Consult factory to negotiate specifications based on dice lot qualifications through sample lot assembly and testing.

<sup>1</sup>Guaranteed by CMR test.

Specifications subject to change without notice.

### ABSOLUTE MAXIMUM RATINGS<sup>1</sup>

Supply Voltage	+33 V
Input Voltage <sup>2</sup>	-15 V to +14 V
Differential Input Voltage <sup>2</sup>	V
Output Short-Circuit Duration	UNLIMITED
Storage Temperature Range	
P, S Package	-65°C to +150°C
Operating Temperature Range	
OP292/OP492 P, S	-40°C to +125°C
Junction Temperature Range	
P, S Package	-65°C to +125°C
Lead Temperature Range (Soldering, 60 sec)	+300°C

Package Type	$\theta_{JA}$ <sup>3</sup>	$\theta_{JC}$	Units
8-Pin Plastic DIP (P)	103	43	°C/W
14-Pin Plastic DIP (P)	83	39	°C/W
8-Pin SO (S)	158	43	°C/W
14-Pin SO (S)	120	36	°C/W

### NOTES

<sup>1</sup>Absolute maximum ratings apply to both DICE and packaged parts, unless otherwise noted.

<sup>2</sup>For supply voltages less than +36 V, the absolute maximum input voltage is equal to the supply voltage.

<sup>3</sup> $\theta_{JA}$  is specified for the worst case conditions, i.e.,  $\theta_{JA}$  is specified for device in socket for P-DIP package;  $\theta_{JA}$  is specified for device soldered in circuit board for SOIC package.

### ORDERING GUIDE

## APPLICATION INFORMATION

### PHASE REVERSAL

The OP492 has built-in protection against phase reversal when the input voltage goes to either supply rail. In fact it is safe for the input to exceed either supply rail by up to 0.6 V with no risk of phase reversal. However, the input should not go beyond the positive supply rail by more than 0.9 V, otherwise the output will reverse phase. If this condition can occur, the problem can be fixed by adding a 5 kΩ current limiting resistor in series with the input pin. With this addition, the input can go to more than 5 V beyond the positive rail without phase reversal.

An input voltage that is as much as 5 V below the negative rail will not result in phase reversal.

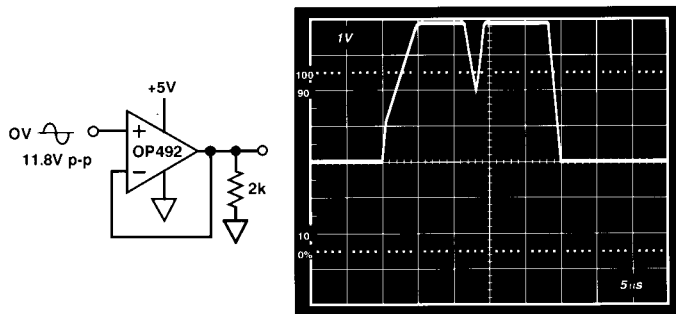

Figure 32. Output Can Reverse Phase If Input Exceeds the Positive Supply ( $V+$ ) by More Than 0.9 V

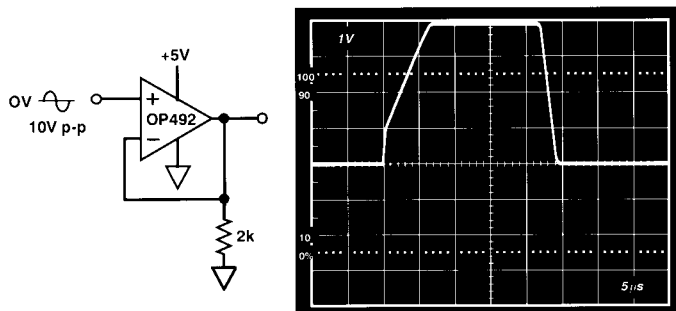

Figure 33. No Negative Rail Phase Reversal, Even with Input Signal at 5 V Below Ground

### Power Supply Considerations

The OP292/OP492 are designed to operate equally well at single +5 V or  $\pm 15$  V supplies. The lowest supply voltage recommended is 4.5 V.

It is a good design practice to bypass the supply pins with a 0.1  $\mu$ F ceramic capacitor. It helps improve filtering of high frequency noise.

For dual supply operation, the negative supply ( $V-$ ) must be applied at the same time, or before  $V+$ . If  $V+$  is applied before  $V-$ , or in the case of a loss of  $V-$  supply, while either input is connected to ground or other low impedance source, excessive input current may result. Potentially damaging levels of input current can destroy the amplifier. If this condition can exist, simply add a 1k or larger resistor in series with the input to eliminate the problem.

### TYPICAL APPLICATIONS

#### Direct Access Arrangement for Telephone Line Interface

Figure 34 shows a +5 V-only transmit/receive telephone line interface for a modem circuit. It allows full duplex transmission of modem signals on a transformer-coupled 600  $\Omega$  line in a differential manner. The transmit section gain can be set for the specific modem device output. Similarly the receive amplifier gain can be appropriately selected based on the modem device input requirements. The circuit operates on a single +5 V supply. The standard value resistors allow the use of a SIP packaged resistor array; this, coupled with a quad op amp in a single package, offers a compact, low part-count solution.

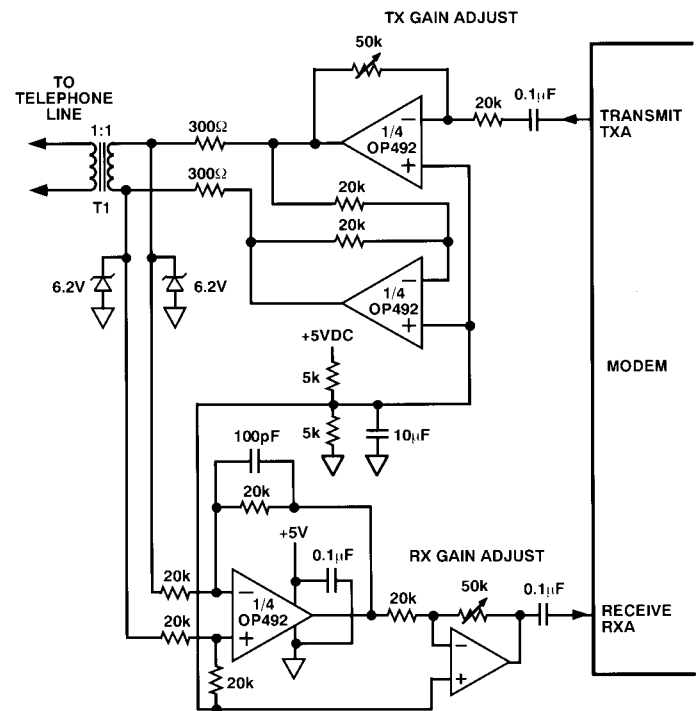

Figure 34. A Universal Direct Access Arrangement for Telephone Line Interface

## A Single Supply Instrumentation Amplifier

A low cost single supply instrumentation amplifier can be built as shown in Figure 35. The circuit utilizes two op amps to form a high input impedance differential amplifier. Gain can be set by selecting resistor  $R_G$  which can be calculated using the transfer function equation. Normally,  $V_{REFERENCE}$  is set to 0 V. Then the output voltage is a function of the gain times the differential input voltage. However, the output can be offset by setting  $V_{REFERENCE}$  from 0 V to 4 V, as long as the input common-mode voltage of the amplifier is not exceeded.

Figure 35. A Single Supply Instrumentation Amplifier

In this configuration, while the output can swing to near zero volts, one needs to be careful because the input's common-mode voltage range cannot operate to zero volts. This is because of the limitation of the circuit configuration where the first amplifier must be able to swing below ground in order to attain a 0 V common-mode voltage, which it cannot do. Depending on the gain of the instrumentation amplifier, the input common-mode extends to within about 0.3 V of zero. One can easily calculate the worst-case common-mode limit for a given gain.

## DAC Output Amplifier

The OP292/OP492 are ideal for buffering the output of single supply D/A converters. Figure 36 shows a typical amplifier used to buffer the output of a CMOS DAC that is connected for single supply operation. To do that, the normally current output 12-bit CMOS DAC (R-2R ladder type) is connected backward to produce a voltage output. This operating configuration necessitates a low voltage reference. In this case, a 1.235 V low power reference is used. The relatively high output impedance (10k) is buffered by the OP292 and at the same time gained up to a much more usable level. The potentiometer provides an accurate gain trim for a 4.095 V full-scale, allowing 1 mV increment per LSB of control resolution.

The DAC8043 device comes in an 8-pin DIP package providing a cost-effective, compact solution to a 12-bit analog channel.

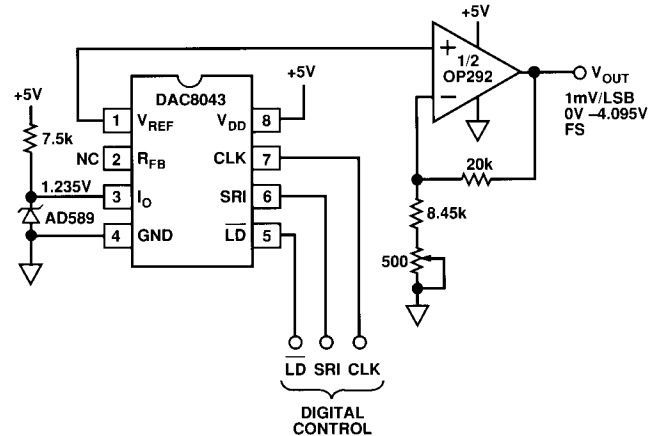

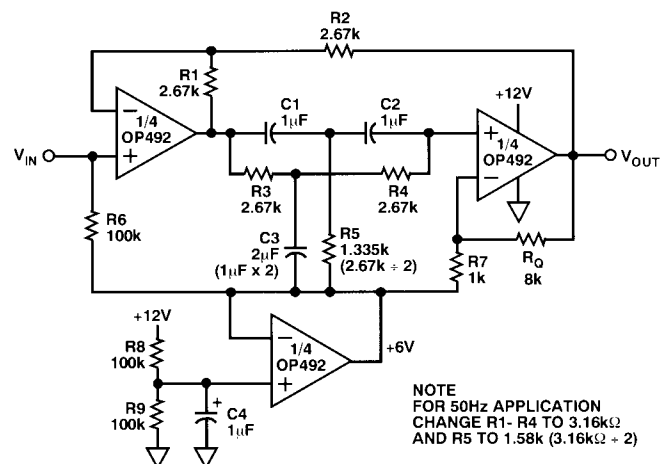

Figure 36. A 12-Bit Single-Supply DAC With Serial Bus Control

## A 50 Hz/60 Hz Single-Supply Notch Filter

Figure 37 shows a notch filter that achieves nearly 30 dB of 60 Hz rejection while powered by only a single 12 V supply. The circuit also works well on +5 V systems. The filter utilizes a twin-T configuration whose frequency selectivity depends heavily on the relative matching of the capacitors and resistors in the twin-T section. Mylar is a good choice for the twin-T's capacitors, and the relative matching of the capacitors and resistors determines the filter's passband symmetry. Using 1% resistors and 5% capacitors produces satisfactory results.

The amount of rejection and the Q of the filter is solely determined by one resistor, and is shown in the table. The bottom amplifier is used to split the supply to bias the amplifier to mid-level. The circuit can be modified to reject 50 Hz by simply changing the resistors in the twin-T section (R1 through R4) from 2.67k to 3.16k, and change R5 to 1/2 of 3.16k. For best results, the common value resistors can be from a resistor array for optimum matching characteristics.

FILTER Q	R <sub>0</sub> (kΩ)	REJECTION (dB)	VOLTAGE GAIN
0.75	1.0	40	1.33
1.00	2.0	35	1.50
1.25	3.0	30	1.60
2.50	8.0	25	1.80
5.00	18	20	1.90
10.00	38	15	1.95

## OP292/OP492

Figure 38. A 4-Pole Bessel Low Pass Filter Using Sallen-Key Topology

### A 4-Pole Bessel Low-Pass Filter

The linear phase filter in Figure 38 is designed to roll off at a voiceband cutoff frequency of 3.6 kHz. The 4 poles are formed by two cascading stages of two-pole Sallen-Key filters.

### A Low Cost, Linearized Thermistor Amplifier

An inexpensive thermometer amplifier circuit can be implemented using low cost thermistors. One such implementation is shown in Figure 39. The circuit measures temperature over the range of 0°C to +70°C to an accuracy of  $\pm 0.3^\circ\text{C}$  as the linearization circuit works well within a narrow temperature range. However, it can measure higher temperature but at a slightly reduced accuracy. To achieve the aforementioned accuracy, the thermistor's nonlinearity must be corrected. This is done by connecting the thermistor in parallel with the 10k in the feedback loop of the first stage amplifier. A constant operating current of 281  $\mu\text{A}$  is supplied by the resistor R1 with the +5 V reference from the REF-195 such that the thermistor's self-heating error is kept below 0.1°C.

In many cases, the thermistor is placed some distance from the signal conditioning circuit. Under this condition, a 0.1  $\mu\text{F}$  capacitor placed across R2 will help to suppress noise pickup.

This linearization network creates an offset voltage which is corrected by summing a compensating current with potentiometer P1. The temperature dependent signal is amplified by the second stage, producing a transfer coefficient of  $-10 \text{ mV}/^\circ\text{C}$  at the output.

To calibrate, a precision decade box can be used in place of the thermistor. For 0°C trim, the decade box is set to 32.650k, and P1 is adjusted until the circuit's output reads 0 V. To trim the circuit at the full-scale temperature of 70°C, the decade box is then set to 1.752k and P2 is adjusted until the circuit reads  $-0.70 \text{ V}$ .

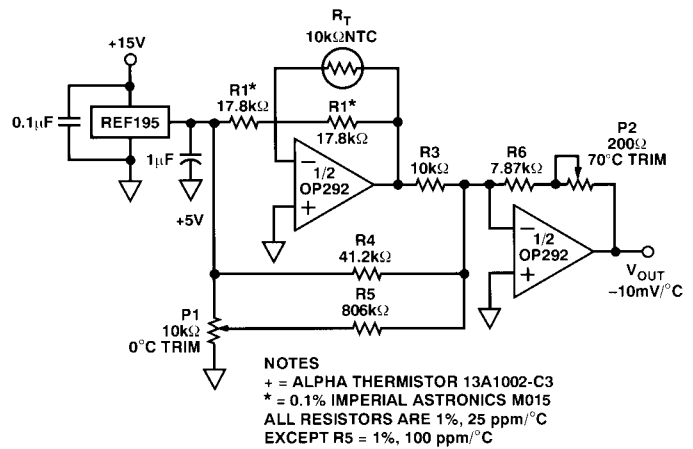

Figure 39. A Low Cost Linearized Thermistor Amplifier

### A Single-Supply Ultrasonic Clamping/Limiting Receiver Amplifier

Figure 40 shows an ultrasonic receiver amplifier using the non-linear impedance of low cost diodes to effectively control the gain for wide dynamic range. This circuit amplifies a 40 kHz ultrasonic signal through a pair of low cost clamping amplifiers before feeding a bandpass filter to extract a clean 40 kHz signal for processing.

The signal is ac-coupled into the false-ground bias node by virtue of the capacitive piezoelectric sensing element. Rather than using an amplifier to generate a supply splitting bias, the false ground voltage is generated by a low cost resistive voltage divider.

Each amplifier stage provides ac gain while passing on the dc self-bias. As long as the output signal at each stage is less than a diode's forward voltage, each amplifier has unrestricted gain to amplify low level signals. However, as the signal strength increases, the feedback diodes begin to conduct, shunting the feedback current, and thus reducing the gain. Although distorting the waveform, the diodes effectively maintain a relatively constant amplitude even with large signals that otherwise would saturate the amplifier. In addition, this design is considerably more stable than the feedback type AGC.

The overall circuit has a gain range from  $-2$  to  $-400$ , where the inversion comes from the bandpass filter stage. Operating with a Q of 5, the filter restores a clean, undistorted signal to the output. The circuit also work well with 5 V supply systems.

# OP292/OP492

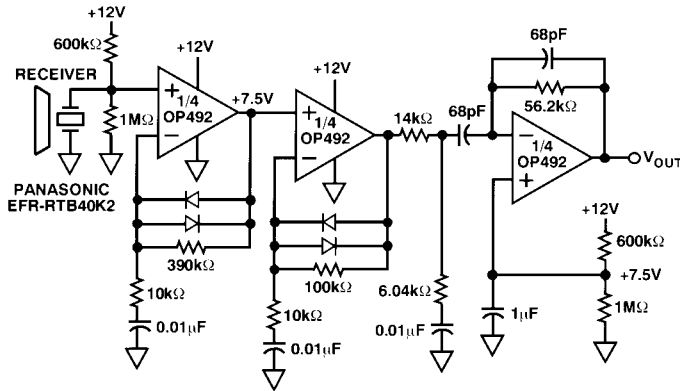

Figure 40. A 40 kHz Ultrasonic Clamping/Limiting Receiver Amplifier

## Precision Single-Supply Voltage Comparator

The OP292/OP492 have excellent overload recovery characteristics, making them suitable for precision comparator applications. Figure 41 shows the saturation recovery characteristics of the OP492. The amplifier exhibits very little propagation delay. The amplifier compares a signal precisely to less than 0.5 mV offset error.

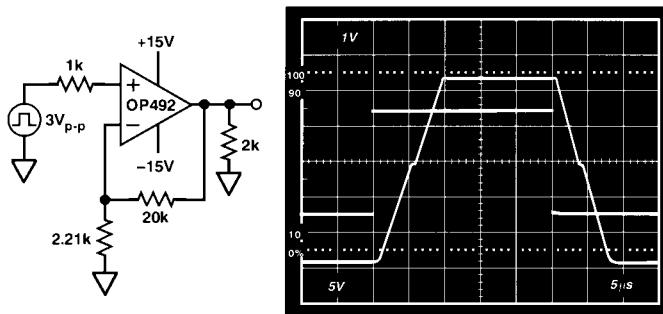

Figure 41. The OP492 Has Fast Overload Recovery for Comparator Applications

## Programmable Precision Window Comparator

The OP292/OP492 can be used for precise level detection such as in test equipment where a signal is measured within a range. Figure 42 shows such an implementation. The threshold voltage level is set by a pair of 12-bit D/A converters. The DACs have serial interface thus minimizing interconnection requirements. The DAC8512 has a control resolution of 1 mV/bit. Thus for 5 V supply operation, maximum DAC output is 4.095 V. However, the OP292 will accept a maximum input of 4.0 V.

Figure 42. Programmable Window Comparator with 12-Bit Threshold Level Control
