#### **PCKV857**

#### **FEATURES**

- ESD classification testing is done to JEDEC Standard JESD22. Protection exceeds 2000 V to HBM per method A114.
- Latch-up testing is done to JEDEC Standard JESD78 which exceeds 100 mA
- Optimized for clock distribution in DDR (Double Data Rate) SDRAM applications as per JEDEC specifications
- 1-to-10 differential clock distribution
- Very low skew (< 100 ps) and jitter (< 100 ps)</li>
- Operation from 2.2 V to 2.7 V AV<sub>DD</sub> and 2.3 V to 2.7 V V<sub>DD</sub>
- SSTL\_2 interface clock inputs and outputs
- CMOS control signal input
- Test mode enables buffers while disabling PLL
- Low current power-down mode
- Tolerant of Spread Spectrum input clock
- Full DDR solution provided when used with SSTL16877 or SSTV16857
- See PCKV856 for I<sup>2</sup>C capable clock driver

#### **DESCRIPTION**

The PCKV857 is a high-performance, low-skew, low-jitter zero delay buffer designed for 2.5 V V<sub>DD</sub> and 2.5 V AV<sub>DD</sub> operation and differential data input and output levels.

The PCKV857 is a zero delay buffer that distributes a differential clock input pair (CLK, CLK) to ten differential pairs of clock outputs (Y[0:9], Y[0:9]) and one differential pair feedback clock outputs (FB<sub>OUT</sub>, FB<sub>OUT</sub>) . The clock outputs are controlled by the clock inputs (CLK, CLK), the feedback clocks (FBIN, FBIN), and the analog power input (AV<sub>DD</sub>). When PWRDWN is high, the outputs switch in phase and frequency with CLK. When PWRDWN is low, all outputs are disabled to high impedance state (3-State), and the PLL is shut down (low power mode). The device also enters the low power mode when the input frequency falls below 20 MHz. An input frequency detection circuit will detect the low frequency condition and after applying a > 20 MHz input signal, the detection circuit turns on the PLL again and enables the outputs.

When AV<sub>DD</sub> is grounded, the PLL is turned off and bypassed for test purposes. The PCKV857 is also able to track spread spectrum clocking for reduced EMI.

The PCKV857 is characterized for operation from 0 to +70 °C.

#### NOTES

- 1. Unused inputs must be held high or low to prevent them from floating.
- 2. DC input signal voltage specifies the allowable DC execution of differential input.
- 3. Differential input signal voltage specifies the differential voltage |VTR VCP| required for switching, where VTR is the true input level and VCP is the complementary input level.
- 4. Differential cross-point voltage is expected to track variations of V<sub>CC</sub> and is the voltage at which the differential signals must be crossing.

Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings
only, and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating
conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

<sup>3.</sup> This value is limited to 3.6 V maximum.

#### NOTE:

- This is intended to operate in the SSTL\_2 type IV unterminated mode without series resistors on the outputs.
   All typical values are at respective nominal V<sub>DDQ</sub>.
- 3. Differential cross-point voltage is expected to track variations of V<sub>DDQ</sub> and is the voltage at which the differential signals must be crossing.
