## 1 FEATURES

- Multi-standard vision IF circuit with alignment-free PLL demodulator without external components
- Internal (switchable) time-constant for the IF AGC circuit
- DTV IF circuit for gain control of digital broadcast TV signals
- Sound IF amplifier with separate AGC circuit for quasi-split sound
- IF circuit can also be used for intercarrier sound
- Analog demodulator for AM sound
- Integrated sound trap and group delay correction
- Video ident function detects the presence of a video signal
- Video source selector with four external CVBS or YC inputs and two analog CVBS outputs with independent source selection for each output
- Two linear inputs for  $1f_H$  or  $2f_H$  RGB signals with source selector; the RGB signals are converted to YUV before A to D conversion; both inputs can also be used as YPbPr input for DVD or set top box
- Integrated anti-alias filters for video Analog to Digital Converters (ADCs)
- Four 10-bit video ADCs for the conversion of CVBS, YC, YUV and down-mixed sound IF signals
- Up to three different A to D converted video channels are available simultaneously (e.g. CVBS, YC and YUV)
- Audio source selector with five stereo inputs for analog audio and two microphone inputs

- Two microphone amplifiers with adjustable gain
- Three analog audio outputs for SCART and line out with independent source selection for each output
- Four 1-bit audio sigma delta ADCs for the conversion of audio and microphone signals
- Three serial data link transmitters for interfacing with the digital video processor at a bit rate of 594 Mbit/s per data link
- Voltage to current converter for driving external east-west power amplifier
- I<sup>2</sup>C-bus transceiver with selectable slave address and maskable interrupt output.

## 2 GENERAL DESCRIPTION

The PNX3000 is an analog front end for digital video processors. It contains an IF circuit for both analog and digital broadcast signals, input selectors and ADCs for analog video and audio signals. The digital output signals are made available via three serial data links.

The IC has a supply voltage of 5 V. The supply voltage of the analog audio part can be 5 V or 8 V, depending on the maximum signal amplitudes that are required.

### Notes

- The supply voltage for the analog audio part of the IC can be 5 V or 8 V. For a supply voltage of 5 V the maximum signal amplitudes at in- and outputs are 1 V (RMS). For a supply voltage of 8 V the maximum amplitudes are 2 V (RMS).
- The RGB inputs can also be used as YPbPr input. The selection is made via the I<sup>2</sup>C-bus. The YPbPr input sensitivity is in accordance with the DVD player specification.

## Analog front end for digital video processors

PNX3000

### 7 FUNCTIONAL DESCRIPTION

#### 7.1 Vision IF

The IF amplifier contains 3 AC-coupled control stages which have a total gain control range of more than 66 dB.

The video signal is demodulated by means of an alignment-free PLL carrier regenerator with an internal VCO. This VCO is calibrated by means of a digital control circuit which uses the external crystal frequency as a reference. The frequency setting for the various standards (33.4 MHz, 33.9 MHz, 38 MHz, 38.9 MHz, 45.75 MHz and 58.75 MHz) is realised via the I<sup>2</sup>C-bus. To improve performance for phase modulated carrier signals the control speed of the PLL can be increased by setting bit FFI.

The AFC output is generated by the digital control circuit of the IF PLL demodulator and can be read via the I<sup>2</sup>C-bus. For fast search tuning systems the window of the AFC can be increased with a factor of three with bus bit AFW.

The AGC-detector operates on top sync or top white level. The demodulation polarity is switched via the I<sup>2</sup>C-bus. The AGC detector capacitor is integrated. The time-constant can be chosen via I<sup>2</sup>C-bus bits AGC1 and AGC0. The AGC has also an external mode which is activated by bit AGCM. In this mode the IF gain is determined by an external voltage on pin DTVIFAGC.

The IC has an integrated sound trap filter. The filter is constructed as a cascade of three separate traps, to realize sufficient suppression of the first and second sound carriers. The trap frequencies are selected via the I<sup>2</sup>C-bus.

The IC has an integrated group delay correction filter. The filter can be switched between the PAL BG curve and a flat group delay response characteristic. This has the advantage that in multi-standard receivers the video SAW filter does not need to be switchable.

#### 7.2 DTV IF

Apart from processing analog TV signals, the IF circuit can also be used to preprocess digital TV signals before they are sent to a DTV channel decoder. For this application the two modes of operation are DTV 1st IF and DTV 2nd IF. For both operating modes the IF PLL must be set to synthesizer mode.

In DTV 1st IF mode only the AGC function of the IF circuit is used, so the DTV channel decoder must be able to handle the 1st IF frequency. Because the AGC detector operates on the down-mixed 2nd IF signal, it is still important to program a valid frequency for the IF VCO. It is recommended to set the frequency of the VCO to a value

that is approximately 4 MHz higher than the incoming 1st IF centre frequency.

In DTV 2nd IF mode the 2nd IF signal is obtained by down-mixing the incoming DTV IF signal with the IF VCO signal. The low-pass filtered DTV 2nd IF signal is available as a differential signal at the DTV output. This signal may have a maximum bandwidth of 10 MHz. The VCO frequency is programmed via the I<sup>2</sup>C-bus in steps of 250 kHz.

In DTV mode the AGC time constant is determined by a capacitor on pin DTVIFAGC. There are two AGC modes: internal and external. In the internal AGC mode the gain is controlled by an internal AGC detector. The external AGC mode is activated by bit AGCM. In this mode the appropriate AGC pin is used as input, so that the IF gain can be controlled by the DTV channel decoder.

The IF PLL has two pins for connection of the PLL loop filters, one for analog TV and one for DTV. This allows each loop filter to be optimized for its application.

#### 7.3 Sound IF

The PNX3000 has a separate sound IF input to enable quasi-split sound applications. The sound IF amplifier is similar to the vision IF amplifier and has a gain control range of about 55 dB. The AGC detector measures the average level of the AM or FM SIF carrier and ensures a constant signal amplitude for the AM demodulator and Quasi-Split Sound (QSS) mixer.

The single reference QSS mixer is realised by a multiplier. In this multiplier the SIF signal is converted to the intercarrier frequency by mixing it with the regenerated picture carrier from the video IF VCO. With this system a high performance stereo sound processing can be achieved.

For applications without a SIF SAW filter the IC can also be used in intercarrier mode. In this mode the composite video signal from the VIF amplifier is fed to the QSS mixer and converted to the intercarrier frequency.

AM sound demodulation is realised in the analog domain by the QSS mixer. The modulated SIF signal is multiplied in phase with the limited SIF signal. The demodulator output signal is low-pass filtered for suppression of the carrier harmonics. The demodulated AM signal can be digitized by one of the audio ADCs.

The QSS mixer can also be used for down-mixing an FM radio IF signal to an intercarrier frequency, so that it can be demodulated by the digital decoder. The IF PLL must be set to synthesizer mode in this case. The preferred solution is to supply the FM radio signal via a

## Analog front end for digital video processors

PNX3000

separate SAW or ceramic filter to the DTV input of the PNX3000. The reason is that the selectivity of a SAW filter for TV sound is not sufficient for FM radio and, if the SIF input is used, no tuner AGC information is available.

For high performance FM radio it is recommended that a 10.7 MHz FM radio IF signal is supplied to the external 2nd SIF input. In this case the IF signal must be filtered by an external bandpass filter, that also functions as an anti-alias filter. The low-pass filter before the 2nd SIF ADC must be bypassed by setting bus bit SLPM.

The IC includes a separate AGC circuit for the 2nd SIF signal. This AGC is needed for intercarrier sound applications and when an external sound IF signal is supplied to the 2nd SIF input. The AGC amplifier is preceded by a second order high-pass filter for suppression of video signal components. The AGC time constant is determined by an external capacitor.

### 7.4 CVBS/YC source selector

The video input selector consists of four independent source selectors, that can select between the CVBS signal coming from the IF part and four external CVBS signals. Two of the external CVBS inputs can also be used as YC input. One selector is used to select the signal for of the primary video channel. A second selector selects the CVBS or YC signal for the secondary channel. The third and fourth selectors are used to select analog outputs CVBS A and B, which can be used for SCART or line output.

The primary channel can be a CVBS or YC signal. If a YC signal is selected for the secondary channel or for the external CVBS outputs A or B, the luminance and chrominance signals are added to obtain a CVBS signal.

The IC has an extra YC input for connection of a 3D comb filter. The comb signal can only be selected for the primary video channel. The input pin CVBS\_DTV allows an analog CVBS signal derived from a digital broadcast (MPEG) signal to be recorded with an analog VCR. This signal cannot be selected for the primary video channel.

The video identification circuit detects the presence of a video signal on the CVBS\_IF input (pin CVBS0). The identification output is normally used to detect transmitters during search tuning and can be read via the I<sup>2</sup>C-bus. The circuit can also be used to monitor the selected primary CVBS or YC signal. Either mode is selected by bit VIM.

### 7.5 RGB/YPbPr source selector

The IC has two RGB inputs. Both inputs can also be used as YPbPr input for connecting video sources with an YPbPr output like a DVD player. The RGB inputs can also be used for fast insertion of RGB signals (for instance on screen display menus) in the primary CVBS signal. The fast insertion switch is located in the digital video processor.

The RGB signals are converted to YUV before further processing. The YUV output signal is digitized by two ADCs. The U and V components have half the bandwidth of the Y signal, therefore the U and V signals are multiplexed and digitized by one ADC.

### 7.6 Video ADCs and anti-alias filters

The PNX3000 contains four video ADCs for analog and digital video broadcast signals. The clock frequency for the ADCs is either 27 MHz or 54 MHz. Two analog signals can be multiplexed at the input of one ADC. Then the clock frequency of the ADC is 54 MHz and the sample frequency of each channel is 27 MHz.

The video ADCs are 10-bit folding ADCs. The sample frequency for standard 1f<sub>H</sub> video signals is 27 MHz. For the YUV channel the sample frequency of the U and V components is half the sample frequency of the Y signal.

For 2f<sub>H</sub> YPbPr or RGB input signals (for instance 480p or 1080i ATSC signals), the frequency that is used to sample the YUV signals is twice as high as for 1f<sub>H</sub> signals. The sample frequency is 54 MHz for Y and 27 MHz for U and V. The high sample frequency requires two data links to transport the video data to the digital video processor.

The anti-alias filters before the ADCs limit the signal bandwidth to prevent aliasing effects. The filters for YUV can be bypassed by means of two separate bits: bit BPY for the Y filter and bit BPUV for the U and V filters. This enables the use of external anti-alias filters with increased bandwidth for 2f<sub>H</sub>, RGB or YPbPr input signals.

Table 1 shows the signal bandwidths and sample rates for the various types of video signals. Table 2 shows which video signals are sent to the digital video processor for both data link modes.

# Analog front end for digital video processors

PNX3000

**Table 1** Overview of anti-alias filter bandwidths and video signal sample rates.

SIGNAL TYPE	SIGNAL COMPONENT	SIGNAL BAND –1.0 dB (MHz)	SIGNAL BAND –3.0 dB (MHz)	SAMPLE FREQUENCY (MHz)
CVBS		8	9	27
YC	Y	8	9	27
	C	8	9	27
YUV 1f <sub>H</sub>	Y	8	9	27
	U	4	4.5	13.5
	V	4	4.5	13.5
YUV 2f <sub>H</sub>	Y	16	18	54
	U	8	9	27
	V	8	9	27
DTV	–	10	12	–
2nd SIF	–	8	9	27

## 7.7 Audio source selectors and A to D converters

The PNX3000 contains two different audio source selectors. The first selector selects which audio signals are routed to the audio ADCs for further processing in the digital domain. The two microphone inputs are also connected to this selector. The selector has two outputs, a primary channel and a secondary channel. The primary audio channel is used for one stereo signal. The secondary audio channel can carry a second stereo signal, or two microphone signals, or one mono signal and one microphone signal or one mono signal and one AM sound signal.

The second selector selects which audio signals are fed to the analog audio outputs for SCART and line out. This selector also has two stereo inputs for demodulated sound signals coming from the digital video processor.

The gain from an external audio input to an analog output is 1. A supply voltage of 5 V allows input and output amplitudes of 1 V (RMS) full scale. The PNX3000 has separate supply voltage pins for the audio selector circuit. To allow for input and output amplitudes of 2 V (RMS) full scale, as required for compliance with the SCART specification, an audio supply voltage of 8 V must be used.

The audio ADCs are 1-bit sigma-delta converters that operate at a clock frequency of 6.75 MHz. The audio A to D clock is synchronous with the video A to D clock, so that audio and video data can be sent over the same data links. The effective audio sample rate is

$$\frac{f_{\text{clk}}}{128} = 52.7 \text{ ksample/s.}$$

## 7.8 Microphone inputs

The IC has two microphone inputs. One microphone input can be used for voice control of the TV set with the help of an intelligent voice command decoder. The second input can be used for connection of a microphone for Karaoke.

To allow the use of microphones with different sensitivities the gain of each microphone amplifier is switchable between two values via the I<sup>2</sup>C-bus.

## 7.9 Clock generation, timing circuitry and black level clamping

The IC contains two PLL circuits that derive the sample clock for the ADCs and the bit and word clocks for the data links from an external reference frequency. The reference frequency must be a stable frequency of either 13.5 MHz or 27 MHz from a crystal oscillator. The internal reference frequency is always 13.5 MHz. If the external frequency is 27 MHz a prescaler must be activated by bus bit FXT.

One PLL is used to multiply the 13.5 MHz reference frequency to the 27 MHz and 54 MHz clock frequencies that are needed for the video ADCs. A second PLL is used to obtain the 297 MHz bit clock for the data link transmitters.

A special timing circuit is used to generate the horizontal and vertical timing pulses that are needed in the IF part, and also for clamping the black level of the selected video signals to a defined value at the output of the video ADCs. The horizontal and vertical timing information of the primary and secondary video channels must be supplied by the digital video processor on pins HV\_PRIM and HV\_SEC. The signal on these pins must consist of a

## Analog front end for digital video processors

PNX3000

horizontal timing pulse that starts just before and ends just after the horizontal sync pulse of the selected video signal. To enable detection of the vertical blanking period, the horizontal pulses must be wider during a number of lines in the vertical blanking interval.

The clamp signal inside the IC is generated with the help of the external horizontal timing pulse and the 13.5 MHz clock. The vertical timing information is used to disable the black level clamp, so that the black level is not disturbed by the vertical sync pulse on the video signal. The clamp pulse for the YUV channel can be derived from the primary or the secondary HV pulse, and is selected by bus bit CLPS.

To avoid signal disturbance, it is possible to disable the black clamps when the horizontal PLL in the digital video processor is not locked to the selected video signal. This is done by bus bit CMP for the primary CVBS channel and bus bit CMS for the secondary CVBS channel.

Special attention is required when the same CVBS input is selected for primary and secondary CVBS channels. In this case the black level clamp loop is only closed for the primary CVBS input. Due to internal offsets this will normally result in a deviation on the black level of the digitized secondary CVBS output.

### 7.10 Data link transmitters

Three serial data links are used for transportation of the digital video and audio data coming from the ADCs in the PNX3000 to the digital video processor. The use of serial data connections results in a considerable reduction in pin count and the number of connection wires that are needed between both ICs.

The communication between data link transmitter and data link receiver consists of two signals, a data signal and a strobe signal. The two signals together contain the data, bit-sync and word-sync information. For optimal EMC performance both data and strobe are low voltage differential signals. The voltage swing on each wire is 300 mV.

Each data word sent over a data link consists of 44 bits: 4 video samples of 10 bits each, 2 audio bits and 2 word-sync bits. The word clock is 13.5 MHz. The data rate on each of the three data links is 594 Mbit/s.

Table 2 shows which video signals are sent to the digital video processor for both data link modes. In the standard mode up to three video channels plus one sound IF signal are digitized and transferred simultaneously over the data links.

The distance between both ICs that are connected via the data link must not be larger than about 10 centimetres. The two wires for each differential signal should be paired in the layout of the printed-circuit board.

### 7.11 I<sup>2</sup>C-bus transceiver

The slave address of the I<sup>2</sup>C-bus transceiver in the PNX3000 has two possible values, selected via the ADR pin. The maximum bus clock frequency is 400 kHz, and the voltage swing of SCL and SDA can be 3.3 V or 5 V. The I<sup>2</sup>C-bus transceiver also has a hardwired IRQ output (open drain and LOW-active) for interruption of the microprocessor when the value of an important status bit in status byte 0 changes. The IRQ signal is maskable with register 0FH.

### 7.12 Power supply circuit

An internal bandgap circuit generates a stable voltage of 1.25 V. This voltage is multiplied to a reference voltage of 2.3 V, and a digital supply voltage of 2.5 V. These two voltages must be decoupled by external capacitors. A  $\frac{1}{2}V_P$  reference voltage for the audio ADCs also requires an external decoupling capacitor. The PNX3000 contains two voltage regulators to supply the SDACs that are used in the digital video processor. Each regulator requires a few external components (one transistor, two resistors and a decoupling capacitor). The output voltage is adjustable between 1.25 V and 3.3 V by selection of external resistors values.

### 7.13 East-west interface

The PNX3000 contains a voltage to current converter that serves as the interface between the voltage output of the digital video processor and the current input of the east-west stage of the vertical deflection amplifier (TDA8358). The transconductance is determined by the value of an external resistor.

# Analog front end for digital video processors

**Table 2** Overview of data link modes

MODE	APPLICATION	DATA LINK 1				DATA LINK 2				DATA LINK 3			
		VIDEO1		AUDIO1		VIDEO2		AUDIO2		VIDEO3		TEST	
0	standard	CVBS/Y <sub>prim</sub>	C	L1	R1	Y <sub>yuv</sub>	U,V	L2	R2	CVBS <sub>sec</sub>	2nd SIF	HV_P	HV_S
1	YUV 2f <sub>H</sub> input	Y <sub>yuv</sub>		L1	R1	U	V	L2	R2	CVBS <sub>sec</sub>	2nd SIF	HV_P	HV_S

## 8 I<sup>2</sup>C-BUS SPECIFICATION

The slave addresses of the IC are given in Table 3. The circuit operates at clock frequencies of up to 400 kHz.

**Table 3** Slave addresses (9A or 9E)

A6	A5	A4	A3	A2	A1	A0	R/W
1	0	0	1	1	A1	1	1/0

Bit A1 is controlled via the ADR pin, when the pin is connected to ground A1 = 0 and when connected to the positive supply line A1 = 1. When this pin is left open it is connected to ground via an internal resistor.

### 8.1 Input control registers

**Notes**

- YUV input is an Y,  $-(B-Y)$  and  $-(R-Y)$  input with the specification:
  - $Y = 1.43 \text{ V (p-p)}$ ;  $U = 1.33 \text{ V (p-p)}$ ;  $V = 1.05 \text{ V (p-p)}$ .
  - These signal amplitudes are based on a colour bar signal with 75 % saturation.
- YPbPr input with the specification:
  - $Y = 1.0 \text{ V (p-p)}$ ;  $Pb = 0.7 \text{ V (p-p)}$ ;  $Pr = 0.7 \text{ V (p-p)}$ .
  - These signal amplitudes are based on a colour bar signal with 100 % saturation.
- RGB input with the specification:
  - $R = 0.7 \times V_{B-W}$ ;  $G = 0.7 \times V_{B-W}$ ;  $B = 0.7 \times V_{B-W}$ .
  - These signal amplitudes are based on a colour bar signal with 100 % saturation.

$T_{sol}$	soldering temperature	for 5 s	–	260	°C
$T_j$	operating junction temperature		–	150	°C
$V_{esd}$	electrostatic discharge voltage	Human Body Model; C = 100 pF; R = 1.5 k $\Omega$ pin SDA all other pins	–	$\pm 1500$	V
			–	$\pm 2000$	V
		Machine Model; C = 200 pF; R = 0 k $\Omega$ pin SDA all other pins	–		
			–	$\pm 150$	V
		–	$\pm 200$	V	

## 10 THERMAL CHARACTERISTICS

SYMBOL	PARAMETER	CONDITIONS	VALUE	UNIT
$R_{th(j-a)}$	thermal resistance from junction to ambient	in free air; note 1	30	K/W

### Note

- The value given for the thermal resistance from junction to ambient should only be considered as an indication. Most of the dissipated heat is conveyed to the ambient air through the Printed-Circuit Board (PCB) on which the IC is mounted. The actual value of the thermal resistance depends on the number of metal layers, size and layout of the PCB, and also on the dissipation of other components on the PCB.

## 11 QUALITY SPECIFICATION

In accordance with document "SNW-FQ-611".

### 11.1 Latch-up performance

At  $T_{amb} = 70$  °C all pins meet the following specification:

- Positive stress test:  $I_{trigger} \geq 100$  mA or  $V_{trigger} \geq 1.5 V_{P(max)}$
- Negative stress test:  $I_{trigger} \leq -100$  mA or  $V_{trigger} \leq -0.5 V_{P(max)}$ .

**Notes**

1. The supply voltage for the analog audio part may have a value between 5 V and 8 V. For a supply voltage of 5 V the maximum amplitude of in- and output signals is 1 V (RMS). For a supply voltage of 8 V the maximum amplitude of in- and output signals is 2 V (RMS).
2. The value of the regulated voltage is determined by the external resistive voltage divider. The voltage range mentioned relates to the voltage at the emitter of the external transistor. The stability of the voltage regulator loop

## Analog front end for digital video processors

PNX3000

depends on the value of the decoupling capacitor  $C_{dec}$  on the emitter of the external transistor. Recommended value

is  $C_{dec} = 1.5 \times \frac{I_o}{V_o} \mu\text{F}$ , with  $I_o$  in mA.

3. This parameter is not tested during production and is just given as application information for the designer of the television receiver.
4. Loop bandwidth  $B_L = 60$  kHz (natural  $f_N = 15$  kHz; damping factor  $d = 2$ ; calculated with top sync level as IF PLL input signal level).
5. The IF PLL demodulator uses an internal VCO (no external LC-circuit required) which is calibrated by means of a digital control circuit which uses the clock frequency of the microcontroller/teletext decoder as a reference. The required IF frequency for the various standards is set via the I<sup>2</sup>C-bus. When the system is locked the resulting IF frequency is very accurate with a deviation from the nominal value of less than 25 kHz.
6. Measured at pin CVBSOUTIF with 10 mV (RMS) top sync input signal at VIF input.
7. So called projected zero point, i.e. with switched demodulator.
8. The signal amplitude at the CVBSOUTIF output depends on the setting of bits VA1 and VA0. The recommended settings for negative modulation (bit PMOD = 0) is VA1 = VA0 = 1. For positive modulation (bit PMOD = 1) the settings VA1 = 1 and VA0 = 0 is recommended. The  $V_{o(dem)(p-p)}$  and  $\Delta V_o$  values specified are valid if the recommended settings are used.
9. Measured in accordance with the test line given in Fig.3. For the differential phase test the peak white setting is reduced to 87 %:
  - a) The differential gain is expressed as a percentage of the difference in peak amplitudes between the largest and smallest value relative to the subcarrier amplitude at blanking level.
  - b) The phase difference is defined as the difference in degrees between the largest and smallest phase angle.
10. This parameter is not tested during production but is guaranteed by the design and qualified by means of matrix batches which are made in the pilot production period.
11. This figure is valid for the complete video signal amplitude (peak white-to-black), see Fig.4.
12. The noise inverter is only active in the 'strong signal mode' (no noise detected in the incoming signal).
13. The test set-up and input conditions are given in Fig.5. Measurement is done with an input signal of 10 mV (RMS).
14. Measured at an input signal of 10 mV (RMS). The S/N is the ratio of black-to-white amplitude to the black level noise voltage (RMS value); B = 5 MHz. Weighted in accordance with CCIR 567.
15. The time-constant of the IF AGC is internal and the speed of the AGC can be set via bus bits AGC1 and AGC0. The AGC response time is also dependent on the acquisition time of the PLL demodulator. The values given are valid for the 'norm' setting (AGC1 = 0 and AGC0 = 1) and when the PLL is in lock.
16. The AFC control voltage is generated by the digital tuning system of the PLL demodulator. This system uses the external crystal frequency as a reference and is therefore very accurate. For this reason no maximum and minimum values are given for the window sensitivity figures. The tuning information is supplied to the tuning system via the I<sup>2</sup>C-bus. Two bits are reserved for this function. The AFC value is valid only when bit LOCK = 1.
17. Exceeding this amplitude leads to intermodulation distortion.
18. The intercarrier sound (2nd SIF) signal is not normally an analog output signal of the IC. It can be made available on the DTV output pins by setting bus bits DSIF = 1 and DFIF = 0.
19. The weighted S/N ratio is measured under the following conditions:
  - a) The vision IF modulator incidental phase modulation for black-to-white jumps must be less than 0.5 degrees
  - b) QSS AF performance of the vision IF modulator, measured with the television demodulator AMF2 (audio output and weighted S/N ratio) better than 60 dB (deviation 27 kHz) for 6 kHz sine wave black-to-white modulation
  - c) Picture-to-sound carrier ratio of the vision IF modulator: PC/SC1 = 13 dB (transmitter)

## Analog front end for digital video processors

PNX3000

- d) The measurements must be carried out with the Siemens SAW filters G3962 for vision IF and G9350 for sound IF. Input level for sound IF 10 mV (RMS) with 27 kHz deviation
- e) The PC/SC ratio at the vision IF input is calculated as the addition of the TV transmitter ratio and the SAW filter PC/SC ratio. This PC/SC ratio is necessary to achieve the  $S/N_W$  values as indicated.
20. The demodulated AM sound signal can be made available in the analog domain on LINE or SCART audio outputs by selecting AM internal (bus bit AMX = 0).
21. The frequency range of the 2nd SIF channel is limited by the 2nd SIF anti-alias filter. If a 10.7 MHz FM radio IF signal is supplied to the external 2nd SIF input; an external 10.7 MHz bandpass filter must be used; and the internal anti-alias filter must be bypassed by setting bus bit SLPM = 1.
22. The cascade of sound trap and group delay correction filter compensates for the group delay pre-distortion of the BG standard, curve A (see "Rec. ITU-R BT.470-4"). The indicated values are the difference between the group delay at 4.43 MHz and the group delay at 10 kHz.
23. The digitized U and V signals have the following polarity:  $U = +(B-Y)$  and  $V = +(R-Y)$ .
24. The S/N ratio is defined as the ratio of the full scale black-to-white amplitude to the black level noise voltage (RMS value).
25. The S/N ratio is defined as the ratio of the full scale peak-to-peak signal amplitude to the zero signal noise voltage (RMS value).
26. The video ADC is specified as a stand-alone circuit. Distortion and noise of the video switch and anti-alias filters is not included.
27. The gain of the microphone amplifiers can be switched between low (17 dB) and high (35 dB). The low gain can be used for microphones with a sensitivity between 5 mV (RMS) and 40 mV (RMS) at 94 dB SPL. The high gain can be used for microphones with a sensitivity of less than 5 mV (RMS) at 94 dB SPL.
28. If the audio supply voltage is 8 V; the 5 V full scale reference voltage for the audio A to D converters at pin 91 (VAADCP) is generated by the IC itself, using the internal bandgap reference. This gives the best power supply rejection ratio for the digital audio outputs. If the audio supply voltage is 5 V; pin 91 must be connected to the external 5 V supply. This results in a reduced power supply rejection ratio for the digital audio outputs.
29. Signals HV\_PRIM and HV\_SEC must be generated by the digital video processor using a 13.5 MHz clock. Where pulse widths are specified in clock pulses, a 13.5 MHz clock is assumed (1 clock pulse is 74.1 ns). To enable detection of the vertical blanking interval, a larger pulse width is used for a number of lines during the vertical blanking period; see Figs 9 and 10.
30. Most timing parameters in this section are expressed in number of clock cycles, abbreviated as ck.
31. The east-west drive circuit is a voltage to current converter circuit, that requires an external conversion resistor. The open drain output transistor can only sink current. The relation between input voltage and output current is as follows:
- $$I_o = \frac{V_i}{4 \times R_{ew}}$$
- where  $R_{ew}$  is the external conversion resistor. The voltage across the external conversion resistor is equal to  $V_i/4$ . The voltage at output pin EWIOUT must not be lower than  $V_i/4 + 0.25$  V. The output current must not be larger than 1.2 mA.
32. The switching levels of pins SDA and SCL are compatible with an external signal amplitude of 3.3 V and 5 V.
33. The IRQ output is an open-drain output; active LOW. The pin IRQ must be loaded with a pull-up resistor.

### 13 TEST AND APPLICATION INFORMATION

#### 13.1 Power supply decoupling

For optimal THD and SNR performance of the analog and digital audio channels, it is important to have stable 5 V and 8 V supply voltages for the audio part of the PNX3000.

The following pins need a stable supply voltage without disturbances in the baseband audio frequency range:

- Pins  $V_{CC(1ASW)}$  and  $V_{CC(2ASW)}$  (pins 98 and 88); the supply voltage for the analog audio switches. The supply current to both of these pins is less than 5 mA. Note that this supply voltage may be 5 V or 8 V.
- Pin VAADCP (pin 91); the 5 V full scale reference for the audio ADCs. The current consumption of this pin is about 0.25 mA. This pin must only be connected to the 5 V supply if an audio supply voltage (pins  $V_{CC(1ASW)}$  and  $V_{CC(2ASW)}$ ) of 5 V is used. If an audio supply of 8 V is used, this pin must not be connected to the 5 V supply voltage. In this case the reference voltage is generated by the IC itself, and only a decoupling capacitor should be connected to this pin.
- Pin  $V_{CC(AADC)}$  (pin 77) is the 5 V supply voltage for the audio ADCs. The supply current for this pin is about 23 mA.

### 15 SOLDERING

#### 15.1 Introduction to soldering surface mount packages

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "Data Handbook IC26; Integrated Circuit Packages" (document order number 9398 652 90011).

There is no soldering method that is ideal for all surface mount IC packages. Wave soldering can still be used for certain surface mount ICs, but it is not suitable for fine pitch SMDs. In these situations reflow soldering is recommended.

#### 15.2 Reflow soldering

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement. Driven by legislation and environmental forces the worldwide use of lead-free solder pastes is increasing.

Several methods exist for reflowing; for example, convection or convection/infrared heating in a conveyor type oven. Throughput times (preheating, soldering and cooling) vary between 100 seconds and 200 seconds depending on heating method.

Typical reflow peak temperatures range from 215 °C to 270 °C depending on solder paste material. The top-surface temperature of the packages should preferably be kept:

- below 225 °C (SnPb process) or below 245 °C (Pb-free process)
  - for all BGA, HTSSON..T and SSOP..T packages
  - for packages with a thickness  $\geq 2.5$  mm
  - for packages with a thickness  $< 2.5$  mm and a volume  $\geq 350$  mm<sup>3</sup> so called thick/large packages.
- below 240 °C (SnPb process) or below 260 °C (Pb-free process) for packages with a thickness  $< 2.5$  mm and a volume  $< 350$  mm<sup>3</sup> so called small/thin packages.

Moisture sensitivity precautions, as indicated on packing, must be respected at all times.

#### 15.3 Wave soldering

Conventional single wave soldering is not recommended for surface mount devices (SMDs) or printed-circuit boards

with a high component density, as solder bridging and non-wetting can present major problems.

To overcome these problems the double-wave soldering method was specifically developed.

If wave soldering is used the following conditions must be observed for optimal results:

- Use a double-wave soldering method comprising a turbulent wave with high upward pressure followed by a smooth laminar wave.
- For packages with leads on two sides and a pitch (e):
  - larger than or equal to 1.27 mm, the footprint longitudinal axis is **preferred** to be parallel to the transport direction of the printed-circuit board;
  - smaller than 1.27 mm, the footprint longitudinal axis **must** be parallel to the transport direction of the printed-circuit board.

The footprint must incorporate solder thieves at the downstream end.

- For packages with leads on four sides, the footprint must be placed at a 45° angle to the transport direction of the printed-circuit board. The footprint must incorporate solder thieves downstream and at the side corners.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Typical dwell time of the leads in the wave ranges from 3 seconds to 4 seconds at 250 °C or 265 °C, depending on solder material applied, SnPb or Pb-free respectively.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

#### 15.4 Manual soldering

Fix the component by first soldering two diagonally-opposite end leads. Use a low voltage (24 V or less) soldering iron applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C.

When using a dedicated tool, all other leads can be soldered in one operation within 2 seconds to 5 seconds between 270 °C and 320 °C.

# Analog front end for digital video processors

PNX3000

## 15.5 Suitability of surface mount IC packages for wave and reflow soldering methods

PACKAGE <sup>(1)</sup>	SOLDERING METHOD	
	WAVE	REFLOW <sup>(2)</sup>
BGA, HTSSON..T <sup>(3)</sup> , LBGA, LFBGA, SQFP, SSOP..T <sup>(3)</sup> , TFBGA, VFBGA, XSON	not suitable	suitable
DHVQFN, HBCC, HBGA, HLQFP, HSO, HSOP, HSQFP, HSSON, HTQFP, HTSSOP, HVQFN, HVSON, SMS	not suitable <sup>(4)</sup>	suitable
PLCC <sup>(5)</sup> , SO, SOJ	suitable	suitable
LQFP, QFP, TQFP	not recommended <sup>(5)(6)</sup>	suitable
SSOP, TSSOP, VSO, VSSOP	not recommended <sup>(7)</sup>	suitable
CWQCCN..L <sup>(8)</sup> , PMFP <sup>(9)</sup> , WQCCN..L <sup>(8)</sup>	not suitable	not suitable

### Notes

- For more detailed information on the BGA packages refer to the “(LF)BGA Application Note” (AN01026); order a copy from your Philips Semiconductors sales office.
- All surface mount (SMD) packages are moisture sensitive. Depending upon the moisture content, the maximum temperature (with respect to time) and body size of the package, there is a risk that internal or external package cracks may occur due to vaporization of the moisture in them (the so called popcorn effect). For details, refer to the Drypack information in the “Data Handbook IC26; Integrated Circuit Packages; Section: Packing Methods”.
- These transparent plastic packages are extremely sensitive to reflow soldering conditions and must on no account be processed through more than one soldering cycle or subjected to infrared reflow soldering with peak temperature exceeding  $217\text{ °C} \pm 10\text{ °C}$  measured in the atmosphere of the reflow oven. The package body peak temperature must be kept as low as possible.
- These packages are not suitable for wave soldering. On versions with the heatsink on the bottom side, the solder cannot penetrate between the printed-circuit board and the heatsink. On versions with the heatsink on the top side, the solder might be deposited on the heatsink surface.
- If wave soldering is considered, then the package must be placed at a  $45^\circ$  angle to the solder wave direction. The package footprint must incorporate solder thieves downstream and at the side corners.
- Wave soldering is suitable for LQFP, QFP and TQFP packages with a pitch (e) larger than 0.8 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.65 mm.
- Wave soldering is suitable for SSOP, TSSOP, VSO and VSSOP packages with a pitch (e) equal to or larger than 0.65 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.5 mm.
- Image sensor packages in principle should not be soldered. They are mounted in sockets or delivered pre-mounted on flex foil. However, the image sensor package can be mounted by the client on a flex foil by using a hot bar soldering process. The appropriate soldering profile can be provided on request.
- Hot bar soldering or manual soldering is suitable for PMFP packages.

## 16 DATA SHEET STATUS

LEVEL	DATA SHEET STATUS <sup>(1)</sup>	PRODUCT STATUS <sup>(2)(3)</sup>	DEFINITION
I	Objective data	Development	This data sheet contains data from the objective specification for product development. Philips Semiconductors reserves the right to change the specification in any manner without notice.
II	Preliminary data	Qualification	This data sheet contains data from the preliminary specification. Supplementary data will be published at a later date. Philips Semiconductors reserves the right to change the specification without notice, in order to improve the design and supply the best possible product.
III	Product data	Production	This data sheet contains data from the product specification. Philips Semiconductors reserves the right to make changes at any time in order to improve the design, manufacturing and supply. Relevant changes will be communicated via a Customer Product/Process Change Notification (CPCN).

### Notes

1. Please consult the most recently issued data sheet before initiating or completing a design.
2. The product status of the device(s) described in this data sheet may have changed since this data sheet was published. The latest information is available on the Internet at URL <http://www.semiconductors.philips.com>.
3. For data sheets describing multiple type numbers, the highest-level product status determines the data sheet status.

## 17 DEFINITIONS

**Short-form specification** — The data in a short-form specification is extracted from a full data sheet with the same type number and title. For detailed information see the relevant data sheet or data handbook.

**Limiting values definition** — Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 60134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

**Application information** — Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors make no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

## 18 DISCLAIMERS

**Life support applications** — These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips Semiconductors customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors for any damages resulting from such application.

**Right to make changes** — Philips Semiconductors reserves the right to make changes in the products - including circuits, standard cells, and/or software - described or contained herein in order to improve design and/or performance. When the product is in full production (status 'Production'), relevant changes will be communicated via a Customer Product/Process Change Notification (CPCN). Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no licence or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified.
