

# **RC4200**

# **Analog Multiplier**

### **Features**

- · High accuracy
- Nonlinearity 0.1% Temperature coefficient – 0.005%/°C
- Multiple functions
- Multiply, divide, square, square root, RMS-to-DC conversion, AGC and modulate/demodulate
- Wide bandwidth 4 MHz
- Signal-to-noise ratio 94 dB

# **Applications**

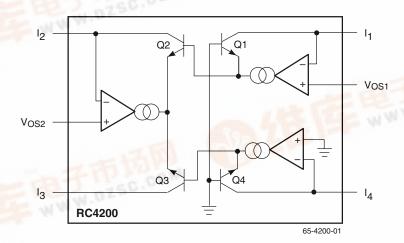

- · Low distortion audio modulation circuits
- · Voltage-controlled active filters
- · Precision oscillators

# Description

The RC4200 analog multiplier has complete compensation for nonlinearity, the primary source of error and distortion. This multiplier also has three onboard operational amplifiers designed specifically for use in multiplier logging circuits. These amplifiers are frequency compensated for optimum AC response in a logging circuit, the heart of a multiplier, and can therefore provide superior AC response.

The RC4200 can be used in a wide variety of applications without sacrificing accuracy. Four-quadrant multiplication, two-quadrant division, square rooting, squaring and RMS conversion can all be easily implemented with predictable accuracy. The nonlinearity compensation is not just trimmed at a single temperature, it is designed to provide compensation over the full temperature range. This nonlinearity compensation combined with the low gain and offset drift inherent in a well-designed monolithic chip provides a very high accuracy and a low temperature coefficient.

# **Block Diagram**

# **Functional Description**

The RC4200 multiplier is designed to multiply two input currents (I<sub>1</sub> and I<sub>2</sub>) and to divide by a third input current (I<sub>4</sub>). The output is also in the form of a current (I<sub>3</sub>). A simplified circuit diagram is shown in the Block Diagram. The nominal relationship between the three inputs and the output is:

$$I_3 = \frac{I_1 I_2}{I_4}$$
 (1)

The three input currents must be positive and restricted to a range of 1  $\mu A$  to 1 mA. These currents go into the multiplier chip at op amp summing junctions which are nominally at zero volts. Therefore, an input voltage can be easily converted to an input current by a series resistor. Any number of currents may be summed at the inputs. Depending on the application, the output current can be converted to a voltage by an external op amp or used directly. This capabilty of combining input currents and voltages in various combinations provides great versatility in application.

Inside the multiplier chip, the three op amps make the collector currents of transistors Q1, Q2 and Q4 equal to their respective input currents (I1, I2, and I4). These op amps are designed with current source outputs and are phase-compensated for optimum frequency response as a multiplier. Power drain of the op amps was minimized to prevent the introduction of undesired thermal gradients on the chip. The three op amps operate on a single supply voltage (nominally -15V) and total quiescent current drain is less than 4 mA. These special op amps provide significantly improved performance in comparison to 741-type op amps.

The actual multiplication is done within the log-antilog configuration of the Q1-Q4 transistor array. These four transistors, with associated proprietary circuitry, were specially designed to precisely implement the relationship.

$$V_{\rm BEN} = \frac{kT}{Q} In \frac{I_{\rm CN}}{I_{\rm SN}} \quad (2)$$

Previous multiplier designs have suffered from an additional undesired linear term in the above equation; the collector current times the emitter resistance. The ICrE term introduces a parabolic nonlinearity even with matched transistors. Fairchild Semiconductor has developed a unique and proprietary means of inherently compensating for this undesired ICrE term. Furthermore, this Fairchild Semiconductor developed circuit technique compensates linearity error over temperature changes. The nonlinearity versus temperature is significantly improved over earlier designs.

From equation (2) and by assuming equal transistor junction temperatures, summing base-to-emitter voltage drops around the transistor array yields:

$$\frac{KT}{q} \left[ In \frac{I_1}{I_{S1}} = In \frac{I_2}{I_{S2}} - In \frac{I_3}{I_{S3}} - In \frac{I_4}{I_{S4}} \right] = 0 \quad (3)$$

This equation reduces to:

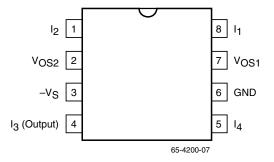

$$\frac{I_1 I_2}{I_3 I_4} = \frac{I_{S1} I_{S2}}{I_{S3} I_{S4}} \tag{4}$$

The rate of reverse saturation current IS<sub>1</sub>IS<sub>2</sub>/IS<sub>3</sub>IS<sub>4</sub>, depends on the transistor matching. In a monolithic multiplier this matching is easily achieved and the rate is very close to unity, typically 1.0±1%. The final result is the desired relationship:

$$I_3 = \frac{I_1 I_2}{I_4}$$
 (5)

The inherent linearity and gain stability combined with low cost and versatility makes this new circuit ideal for a wide range of nonlinear functions.

# **Pin Assignments**

# **Absolute Maximum Ratings**

Parameter		Min.	Max.	Unit

Supply Current	I <sub>1</sub> = I <sub>2</sub> = I <sub>4</sub> = 150 μA T <sub>A</sub> = +25°C			4.0			4.0	mA

#### Notes:

- 1. Refer to Figure 6 for example.
- 2. The input circuits tend to become unstable at I<sub>1</sub>, I<sub>2</sub>, I<sub>4</sub> < 50  $\mu$ A and linearity decreases when I<sub>1</sub>, I<sub>2</sub>, I<sub>4</sub> > 250  $\mu$ A (eq. @ I<sub>1</sub> = I<sub>2</sub> = 500  $\mu$ A, nonlinearity error  $\approx$  0.5%).
- 3. These specifications apply with output (I<sub>3</sub>) connected to an op amp summing junction. If desired, the output (I<sub>3</sub>) at pin (4) can be used to drive a resistive load directly. The resistive load should be less than 700Ω and must be pulled up to a positive supply such that the voltage on pin (4) stays within a range of 0 to +5V.

# **Applications Discussion**

### **Current Multiplier/ Divider**

The basic design criteria for all circuit configurations using the RC4200 multiplier is contained in equation (1), that is,

$$I_3 = \frac{I_1 I_2}{I_4}$$

The current-product-balance equation restates this as:

$$I_1 I_2 = I_3 I_4$$
 (6)

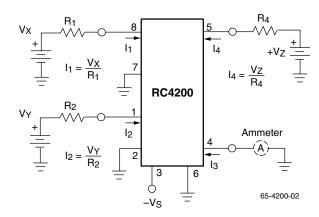

Figure 1. Current Multiplier/Divider

## **Dynamic Range and Stability**

The precision dynamic range for the RC4200 is from +50 µA

to  $+250 \,\mu\text{A}$  inputs for I<sub>1</sub>, I<sub>2</sub> and I<sub>4</sub>. Stability and accuracy degrade if this range is exceeded.

To improve the stability for input currents less than 50  $\mu$ A, filter circuits (RsCs) are added to each input (see Figure 2).

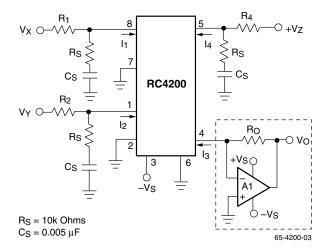

Figure 2. Current Multiplier/Divider with Filters

Amplifier A1 is used to convert the I3 current to an output voltage.

Multiplier:  $Vz = constant \neq 0$ Divider:  $Vy = constant \neq 0$ 

### Voltage Multiplier/Divider

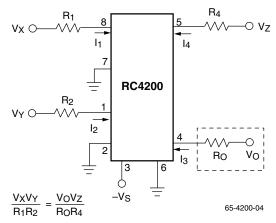

Figure 3. Voltage Multiplier/Divider

Solving for 
$$V_0 = \frac{V_X V_Y - R_0 R_4}{V_Z - R_1 R_2}$$

For a multiplier circuit  $V_Z = V_R = constant$ 

Therefore: 
$$V_0 = V_X V_Y K$$
 where  $K = \frac{R_0 R_4}{V_R R_1 R_2}$ 

For a divider circuit  $V_Y = V_R = constant$ 

Therefore: 
$$V_0 = \frac{V_X}{V_Z} K$$
 where  $K = \frac{V_R R_0 R_4}{R_1 R_2}$ 

#### **Extended Range**

The input and output voltage ranges can be extended to include 0 and negative voltage signals by adding bias currents. The RsCs filter circuits are eliminated when the input and biasing resistors are selected to limit the respective currents to  $50~\mu A$  min. and  $250~\mu A$  max.

### **Extended Range Multiplier**

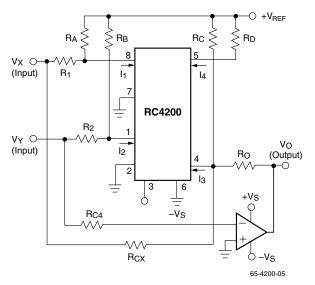

Figure 4. Extended Range Multiplier

Resistors  $R_a$  and  $R_b$  extend the range of the  $V_X$  and  $V_Y$  inputs by picking values such that:

$$\begin{split} &I_{1}(\text{min.}) = \frac{V_{X}(\text{min.})}{R_{1}} + \frac{V_{REF}}{R_{a}} = 50 \ \mu\text{A}, \\ &\text{and} \ I_{1}(\text{max.}) = \frac{V_{X}(\text{max.})}{R_{1}} + \frac{V_{REF}}{R_{a}} = 250 \ \mu\text{A}, \\ &\text{also} \ I_{2}(\text{min.}) = \frac{V_{Y}(\text{min.})}{R_{2}} + \frac{V_{REF}}{R_{b}} = 50 \ \mu\text{A}, \\ &\text{and} \ I_{2}(\text{max.}) = \frac{V_{Y}(\text{max.})}{R_{2}} + \frac{V_{REF}}{R_{b}} = 250 \ \mu\text{A}. \end{split}$$

Resistor RC supplies bias current for I3 which allows the output to go negative.

Resistors RCX and RCY permit equation (6) to balance, ie.:

$$\begin{split} &\left(\frac{v_X}{R_1} + \frac{v_{REF}}{R_a}\right) \left(\frac{v_Y}{R_2} + \frac{v_{REF}}{R_b}\right) = \left(\frac{v_0}{R_0} + \frac{v_{REF}}{R_C} + \frac{v_X}{R_{CX}} + \frac{v_Y}{R_{CY}}\right) \left(\frac{v_{REF}}{R_D}\right) \\ &\frac{v_Y v_X}{R_1 R_2} + \frac{v_X v_{REF}}{R_1 R_b} + \frac{v_Y v_{REF}}{R_2 R_a} + \frac{v_{REF}}{R_a R_b} = \\ &\frac{v_0 v_{REF}}{R_0 R_d} + \frac{v_X v_{REF}}{R_{cx} R_d} + \frac{v_Y v_{REF}}{R_{CY} R_d} + \frac{v_{REF}}{R_c R_d} \end{split}$$

## **Cross-Product Cancellation**

Cross-products are a result of ths  $V_XV_R$  and  $V_YV_R$  terms. To the extend that  $R_1R_b = R_{CX}R_D$ , and  $R_2R_a = R_{CY}R_d$  cross-product cancellation will occur.

### **Arithmetic Offset Cancellation**

The offset caused by the  $V_{REF}^2$  term will cancel to the extent that  $R_aR_b = R_0R_d$ , and the result is:

$$\frac{V_Y V_X}{R_1 R_2} = \frac{V_0 V_{REF}}{R_0 R_d} \text{ or } V_0 = V_X V_Y K$$

where 
$$K = \frac{R_0 R_d}{V_{REF} R_1 R_2}$$

### **Resistor Values**

Inputs

$$\begin{aligned} &V_X(\text{min.}) \leq V_X \leq V_X(\text{max.}) \\ &\Delta V_X = V_X(\text{max.}) - V_X(\text{min.}) \\ &V_Y(\text{min.}) \leq V_Y \leq V_Y(\text{max.}) \\ &\Delta V_Y = V_Y(\text{max.}) = V_Y(\text{min.}) \\ &V_{REF} = \text{Constant (+7V to +18V)} \end{aligned}$$

$$K = \frac{V_0}{V_X V_Y} (Design Requirements)$$

$$\begin{split} R_1 &= \frac{\Delta V_X}{200 \mu A}, \, R_2 = \frac{\Delta V_Y}{200 \mu A}, \, R_d = \frac{V_{REF}}{250 \mu A} \\ R_a &= \frac{\Delta V_X V_{REF}}{250 \mu A \Delta V_X - 200 \mu A \, V_X(max.)} \end{split}$$

$$R_b = \frac{\Delta V_X V_{REF}}{250\mu A \Delta V_Y - 200\mu A \ V_Y(max.)}$$

$$R_{c} = \frac{R_{a}R_{b}}{R_{d}}, R_{CX} = \frac{R_{1}R_{b}}{R_{d}}, R_{cy} = \frac{R_{2}R_{a}}{R_{d}}$$

$$R_0 = \frac{\Delta V_X \Delta V_Y K}{160 \mu A}$$

# **Multiplying Circuit Offset Adjust**

 $10K \le R_5 = R_9 = R_{16} \le 50K$ 

 $R_7 = R_{11} = R_{14}, = 100\Omega$ 

 $R_6 = R_{10} = 100\Omega \text{ (Vs/0.05)}$ 

 $R_{15} = 100\Omega \text{ (Vs/0.10)}$ 

 $R_8 = R_1 \mid \mid R_a$ 

 $R_{12} = R_2 | | R_b$ 

 $R_{13} = R_0 || R_C || R_{CX} || R_{CY}$ 

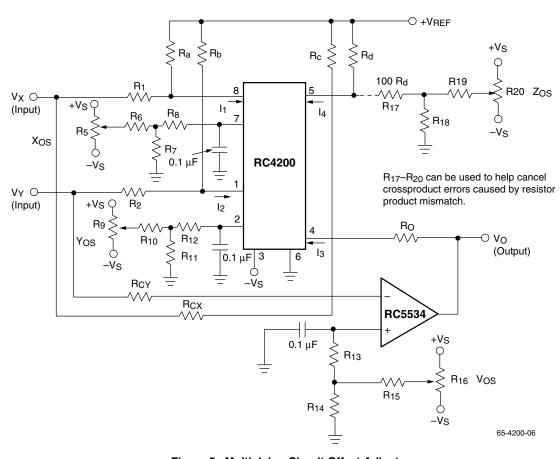

Figure 5. Multiplying Circuit Offset Adjust

### **Procedure**

- 1. Set all trimmer pots to 0V on the wiper.
- 2. Connect VX input to ground. Put in a full scale square wave on VY input. Adjust XOS(R5) for no square wave on V0 output (adjust for 0 feedthrough).
- 3. Connect Vy input to ground. Put in a full scale square wave on Vx input. Adjust Yos(R9) for no square wave on V0 output (adjust for 0 feedthrough).
- Connect V<sub>X</sub> and V<sub>Y</sub> to ground. Adjust V<sub>OS</sub>(R<sub>16</sub>) for 0V on V<sub>0</sub> output.

# **Extended Range Divider**

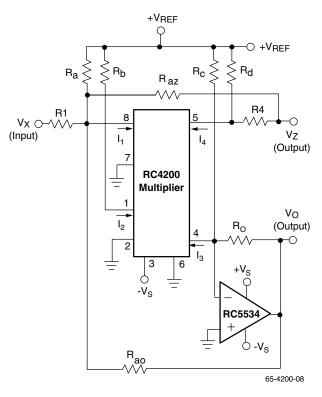

Figure 6. Extended Range Divider

As with the extended range multiplier, resistors  $R_{az}$  and  $R_{ao}$  are added to cancel the cross-product error caused by the biasing resistors, i.e.

$$\begin{split} & \left(\frac{v_{X}}{R_{1}} + \frac{v_{0}}{R_{ao}} + \frac{v_{Z}}{R_{az}} + \frac{v_{REF}}{R_{a}}\right) \left(\frac{v_{REF}}{R_{b}}\right) = \left(\frac{v_{0}}{R_{0}} + \frac{v_{REF}}{R_{C}}\right) \left(\frac{v_{Z}}{R_{4}} + \frac{v_{REF}}{R_{D}}\right) \\ & \frac{v_{X}v_{REF}}{R_{1}R_{b}} + \frac{v_{0}v_{REF}}{R_{ao}R_{b}} + \frac{v_{Z}v_{REF}}{R_{az}R_{b}} + \frac{v_{REF}^{2}}{R_{a}R_{b}^{2}} = \\ & \frac{v_{0}v_{Z}}{R_{0}R_{4}} + \frac{v_{0}v_{REF}}{R_{0}R_{d}} + \frac{v_{Z}v_{REF}}{R_{4}R_{c}} + \frac{v_{REF}^{2}}{R_{c}R_{d}^{2}} \end{split}$$

To cancel cross-product and arithmetic offset:

$$R_{ao}R_b = R_0R_d$$
,  $R_{az}R_b = R_4R_c$  and  $R_aR_b = R_cR_d$ 

and the result is:

$$\frac{\mathbf{V}_{\mathbf{X}}\mathbf{V}_{\mathrm{REF}}}{\mathbf{R}_{1}\mathbf{R}_{b}} = \frac{\mathbf{V}_{0}\mathbf{V}_{\mathbf{Z}}}{\mathbf{R}_{0}\mathbf{R}_{4}} \quad \text{or} \quad \mathbf{V}_{0} = \frac{\mathbf{V}_{\mathbf{X}}}{\mathbf{V}_{\mathbf{Z}}\mathbf{K}}$$

where 
$$K = \frac{V_{REF}R_0R_4}{R_1R_b}$$

Notice that it is necessary to match the above resistor cross-products to within the amount of error tolerable in the output offset, i.e., with a 10V F.S. output, 0.1% resistor cross-product match will give 0.1% x 10V. untrimmable output offset voltage.

#### **Resistor Values**

#### **Inputs:**

 $V_X(min.) \le V_X \le V_X(max.)$   $\Delta V_X = V_X(max.) = V_X(min.)$   $V_Z(min.) \le V_Z \le V_Z(max.)$   $\Delta V_Z = V_Z(max.) = V_Z(min.)$  $V_{REF} = Constant (+7V to +18V)$ 

### **Outputs:**

$$\begin{split} &V_0 \text{ (min.)} \leq V_0 \leq V_0 \text{ (max.)} \\ &\Delta V_0 = V_0 \text{ (max.)} = V_0 \text{ (min.)} \\ &K = \frac{V_0 V_Z}{V_X} \text{(Design Requirement)} \\ &R_0 = \frac{\Delta V_0}{750 \mu A}, R_b = \frac{\Delta V_{REF}}{250 \mu A}, R_4 = \frac{\Delta V_Z}{200 \mu A} \end{split}$$

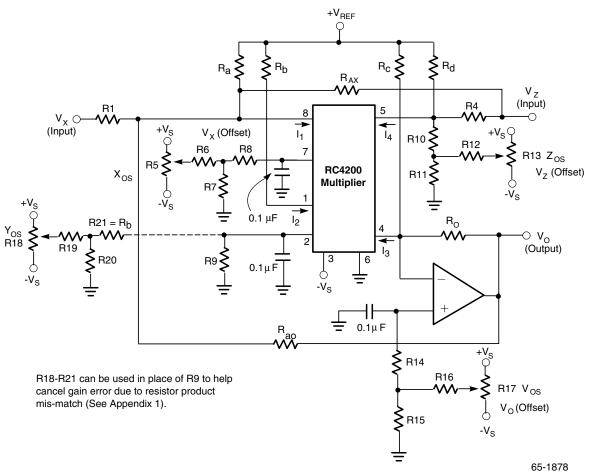

$$R_{c} = \frac{\Delta V_{0} V_{REF}}{750 \mu A \Delta V_{0} - 700 \mu A V_{0} (max.)}$$

$$R_{d} = \frac{\Delta V_{X} V_{REF}}{250\mu A \Delta V_{Z} - 200\mu A \ V_{Z}(max.)}$$

$$R_{a} = \frac{R_{c}R_{d}}{R_{b}}, R_{az} = \frac{R_{c}R_{4}}{R_{b}}, R_{ao} = \frac{R_{0}R_{d}}{R_{b}}$$

$$R_1 = \frac{\Delta V_0 \Delta V_Z}{600 \mu AK}$$

# **Divider Circuit with Offset Adjustment**

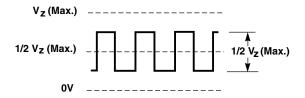

General	Example: Two-Quad Div	/ider
$10K \le R_5 = R_{13} = R_{17} \le 50K$	$V_0 = K(V_X/V_Z), K = k, V_R$	EF = +VS = +15V
$R_7 + R_8 \approx R_1    R_a    R_{az}    R_{a0}$	$-10 \le V_X \le +10$ , therefore	$\Delta V X = 20$
R <sub>6</sub> ≈ R <sub>7</sub> (V <sub>S</sub> /0.05)	$0 \le V_Z \le +10$ , therefore $\Delta$	Vz = 20
$R_9 = R_b$	$-10 \le V_0 \le +10$ , therefore	$\Delta V_0 = 20$
$R_{10} \approx 100 \text{ x } R_4$	$R_0 = 26.7K$	$R_1 = 333K$
$R_{11} = 20K$	$R_b = 60K$	$R_5$ , $R_{13}$ , $R_{17} = 10K$
$R_{12} = 100K$	$R_4 = 50K$	$R_{7}$ , $R_{15} = 1K$
$R_{14} + R_{15} \approx R_0 \mid \mid R_C$	$R_{C} = 37.5K$	$R_8$ , $R_{11} = 20K$
R <sub>16</sub> ≈ R <sub>15</sub> (V <sub>S</sub> /0.10)	$R_d = 300K$	$R_{6}$ , $R_{9}$ , $R_{16} = 300$ K
	$R_a = 187.5K$	$R_{10} = 4.7M$
	$R_{az} = 31.25$	$R_{12} = 100K$
	$R_{ao} = 133K$	

Figure 7. Divider Circuit with Offset Adjustment

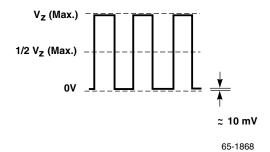

### **Divider Circuit Offset Adjustment Procedure**

- 1. Set each trimmer pot to 0V on the wiper.
- Connect VX (input) to ground. Put a DC voltage of approximatey 1/2 VZ (max.) DC on the VZ (input) with an AC (squarewave is easiest) voltage of 1/2 VZ (max.) peak-to-peak superimposed on it. Adjust XOS (R5) for zero feedthrough. (No AC at V0)

 Connect V<sub>X</sub> (input) to V<sub>Z</sub> (input) and put in the 1/2 V<sub>Z</sub>(max.) DC with an AC of approximately 20 mV less than V<sub>Z</sub>(max.).

Adjust Zos (R<sub>13</sub>) for zero feedthrough.

- 4. Return V<sub>X</sub> (Input) to ground and connect V<sub>Z</sub>(max.) DC on V<sub>Z</sub>(input). Adjust output V<sub>OS</sub>(R<sub>17</sub>) for V<sub>O</sub> = 0V<sub>O</sub>
- 5. Connect VX (input) to VZ (input) and and in VZ (max.) DC. (The output will equal K.) Decrease the input slowly until the output (V<sub>0</sub> K) deviates beyond the desired accuracy. Adjust Z<sub>OS</sub> to bring it back into tolerance and return to Step 4. Continue steps 4 and 5 until VZ reduces to the lowest value desired.

Notice that as the input to VX and VZ gets closer to zero (an illegal state) the system noise will predominate so much that an integrating voltmeter will be very helpful.

## Square Root Circuit $V_0 = N\sqrt{V_X}$

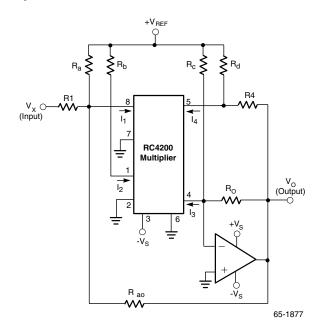

Figure 8.

$$\begin{split} &\frac{V_X V_{REF}}{R_1 R_b} + \frac{V_{REF}}{R_a R_b}^2 + \frac{V_0 V_{REF}}{R_{ao} R_b} = \frac{V_0^2}{R_0 R_4} + \frac{V_0 V_{REF}}{R_c R_4} + \frac{V_0 V_{REF}}{R_0 R_d} + \frac{V_{REF}}{R_c R_d}^2 \end{split}$$
 If  $R_a R_b = R_c R_d$  and  $R_{ao} R_b R_0 R_d + R_{ao} R_b R_c R_4 = R_c R_d R_0 R_4$  Then  $\frac{V_0^2}{R_0 R_4} = \frac{V_X V_{REF}}{R_1 R_b}$  or  $V_0^2 = V_X K$  where  $K = \frac{V_{REF} R_0 R_4}{R_1 R_b}$  and  $V_0 = N \sqrt{V_X}$  where  $N = \sqrt{K}$ 

$$0 \le V_X \le V_X(\text{max.}) \text{ and } V_0(\text{max.}) = N \sqrt{V_X(\text{max.})}$$

$$N = \frac{V_0}{\sqrt{V_X}} (Design Requirements)$$

$$R_1 = \frac{V_0(\text{max.})^2}{74\mu \text{A N}^2}$$

$$R_a = R_d = \frac{V_{REF}}{50\mu A}$$

$$R_b = R_c = \frac{V_{REF}}{150\mu A}$$

$$R_4 = \frac{V_0(\text{max.})}{50\mu\text{A}}$$

$$R_{ao} = \frac{V_0(\text{max.})}{125 \text{ mA}}$$

$$R_0 = \frac{V_0(\text{max.})}{225 \mu \text{A}}$$

# **Square Root Circuit Offset Adjust**

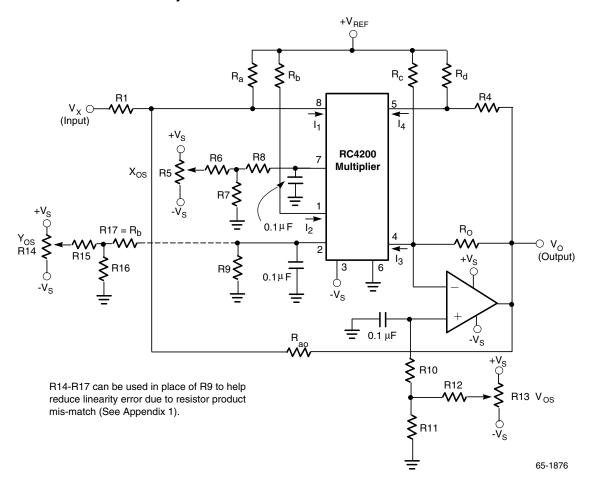

Figure 9. Square Root Circuit Offset Adjust

$$10K \le R_5 = R_{13} \le 50K$$
$$R_7 = 100\Omega$$

$$R_6 = R_7 \frac{V_S}{0.05}$$

$$R_8 = R_1 \parallel R_a \parallel R_{ao}$$

$$R_9 = R_b$$

$$R_{10} = R_0 \| R_C$$

$$R_{11} = 100\Omega$$

$$R_{12} = R_{11} \frac{V_S}{0.1}$$

### **Procedure**

- 1. Set both trimmer pots to 0V on the wiper.
- 2. Put in a full scale (0 to V<sub>X</sub>(max.) squarewave on V<sub>X</sub> input. Adjust X<sub>OS</sub>(R5) for proper peak-to-peak amplitude on V<sub>0</sub> output. (Scaling adjust)
- Connect V<sub>X</sub> input to ground. Adjust VOS(R13) for 0V on V<sub>0</sub> output.

# Squaring Circuits $V_0 = K V \chi^2$

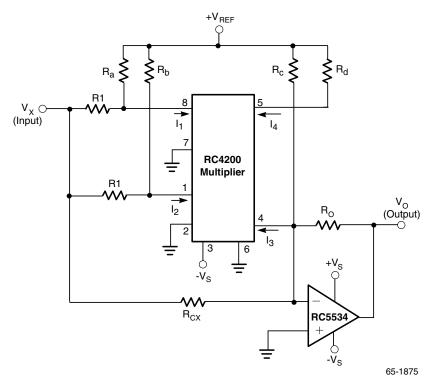

Figure 10. Squaring Circuit

$$\frac{{{{V_X}^2}}}{{{R_1}^2}} + \frac{{2{V_X}{V_{REF}}}}{{{R_1}{R_a}}} + \frac{{{V_{REF}}^2}}{{{R_a}^2}} = \frac{{{V_0}{V_{REF}}}}{{{R_0}{R_d}}} + \frac{{{V_{REF}}^2}}{{{R_c}{R_d}}} + \frac{{{V_X}{V_{REF}}}}{{{R_c}{R_d}}}$$

if 
$$R_a^2 = R_c R_d$$
 and  $R_1 R_a = 2R_{CX} R_D$ 

then 
$$\frac{V_0 V_{REF}}{R_0 R_d} = \frac{V_X^2}{R_1^2}$$
 or  $V_0 = K V_X^2$  where  $K = \frac{R_0 R_d}{V_{REF} R_1^2}$ 

 $V_X(min.) \le V_X \le V_X(max.)$   $\Delta V_X = V_X(max.) - V_X(min.)$ 

$$K = \frac{V_0}{V_X^2}$$
 (Design Requirement)

$$R_1 = \frac{\Delta V_X}{200 \mu A}$$

$$R_{a} = \frac{\Delta V_{X} V_{REF}}{250\mu A \Delta V_{X} - 200\mu A \ V_{X}(max.)}$$

$$R_{d} = \frac{V_{REF}}{250\mu A}$$

$$R_c = \frac{R_a^2}{R_d}$$

$$R_{cx} = \frac{R_1 R_a}{2R_d}$$

$$R_0 = \frac{\Delta V_X^2 K}{160 \mu A}$$

## **Squaring Circuits Offset Adjust**

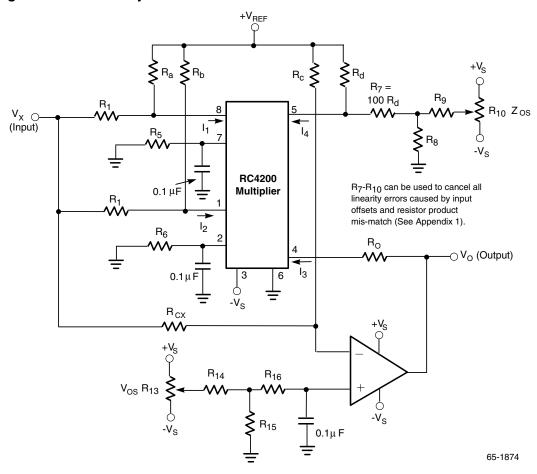

Figure 11. Squaring Circuit Offset Adjust

$$10K \le R_{10} = R_{11} \le 50K$$

$$R_8, R_{15} = 100\Omega$$

$$R_9, R_{14} = 100\Omega \frac{V_S}{0.1}$$

$$R_5, R_6 = R_1 || R_a$$

$$R_{16} = R_0 \parallel R_c \parallel R_a$$

### **Procedure**

- 1. Set both trimmer pots to 0V on the wiper.
- Put in a full scale (±VX) squarewave on VX input. Adjust ZOS(R10) for uniform output.
- 3. Connect  $V_X$  input to ground. Adjust  $V_{OS}(R_{11})$  for 0V on  $V_0$  outputs.

# **Appendix 1—System Errors**

There are four types of accuracy errors which affect overall system performance. They are:

- Nonimearity—Incremental deviation from absolute accuracy. See Note 1.
- Scaling Error—Linear deviation from absolute accuracy.
- Output Offset—Constant deviation from absolute accuracy.
- Feedthrough.—Cross-product errors caused by input offsets and external circuit limitations. See Note 2.

This nonlinearity error in the transfer function of the RC4200 is  $\pm 0.1\%$  maximum ( $\pm 0.03$  maximum for the RC4200A). That is,

$$I_3 = \frac{I_1 I_2}{I_4} \pm 0.1\% \text{ F.S.}^{(4)}$$

The other system errors are caused by voltage offsets on the inputs of the RC4200 and can be as high as  $\pm 3.0\%$  ( $\pm 2.0\%$  for RC4200A).

$$V_0 = \frac{V_X V_Y}{V_Z} \frac{R_0 R_4}{R_1 R_2} \pm 3.0\% \text{ F.S.}^{(3)(4)}$$

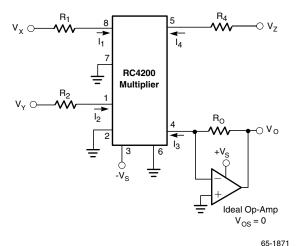

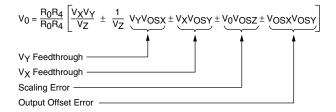

Figure 12.

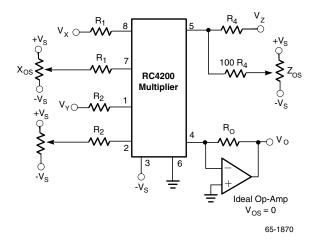

### Notes:

- 1. The input circuits tend to become unstable at I1, I2, I4 < 50  $\mu$ A and linearity decreases when I1, I2, I4 > 250  $\mu$ A (e.g., @ I1 = I2 = 500 $\mu$ A nonlinearity error  $\approx$  0.5%).
- This section will not deal with feedthrough which is proportional to frequency of operation and caused by stray capacitance and/or bandwidth limitations. (refer to Figure 12.)
- Not including resistor tolerance or output offset on the operational amplifier.
- 4. For 50  $\mu$ A  $\leq$  I<sub>1</sub>, I<sub>2</sub>, I<sub>4</sub>  $\leq$  250  $\mu$ A.

## **Errors Caused by Input Offsets**

System errors can be greatly reduced by externally trimming the input offset voltages of the RC4200. (±3.0% F.S. for RC4200 and ±0.1% for RC4200A.)

If Xos = Xosx, Yos = Yosy, Zos = -Vosz,

then 
$$V_{O} \frac{V_{X}V_{Y}}{V_{Z}} \frac{R_{0}R_{4}}{R_{1}R_{2}} \pm 0.3\% \text{ F.S.}^{3)}$$

Figure 13. RC4200 with Input Offset Adjustment

# **Extended Range Circuit Errors**

The extended range configurations have a disadvantage in that additional accuracy errors may be introduced by resistor product mismatching.

### Multiplier

An error in resistor product matching will cause an equivalent feedthrough or output offset error. See Figure 6.

 $R_1R_b = R_{CX}R_d \pm \alpha$ ,  $V_X$  feedthrough  $(V_Y = 0) = I\alpha V_X$ 

 $R_2R_a = R_{CY}R_d \pm \beta$ , VY feedthrough  $(V_X = 0) = \pm \beta V_Y$ 

 $R_aR_b = R_cR_d \pm \gamma$ ,  $V_0$  offset  $(V_X = V_Y = 0) = \pm \gamma V_{REF}^*$ 

#### Note:

 Output offset errors can always be trimmed out with the output op amp offset adjust, VOS (R16).

## **Reducing Mismatch Errors**

You need not use 0.01% resistors to reduce resistor product mismatch errors. Here are a couple of ways to obtain maximum accuracy out of the extended range multiplier (see Figure 4) using 1% resistors.

#### Method 1

VX feedthrough, for example, occurs when VY = 0 and VOSY  $\neq$  0. This VX feedthrough will equal  $\pm$ VXVOSY. Also, if VOSZ  $\neq$  0, there is a VX feedthrough equal to VXVOSZ. A resistor-product error of  $\alpha$  will cause a VX feedthrough of  $\pm \alpha$ VX. Likewise, VY feedthrough errors are:  $\pm$ VYVOSX,  $\pm$ VYVOSZ and  $\pm$  $\beta$ VY

Total feedthrough:

 $\pm V_X V_{OSY} \pm V_Y V_{OSX} \pm \alpha V_X \pm \beta V_Y \pm (V_X + V_Y) V_{OSZ}$ 

By carefully abusing  $X_{OS}(R_5)$ ,  $Y_{OS}(R_9)$  and  $Z_{OS}(R_{20})$  this equation can be made to very nearly equal zero and the feedthrough error will practically disappear.

A residual of set will probably remain which can be trimmed outwith  $V_{OS}(R_{16})$  at the output of amp.

#### Method 2

Notice that the ratios of  $R_1R_b$ : $R_CXR_d$  and  $R_2R_a$ : $R_CYR_d$  are both dependent of  $R_d$  also that  $R_1$ ,  $R_2$ ,  $R_a$  and  $R_b$  are all functions of the maximum input requirements. By designing a multiplier for the same input ranges on both  $V_X$  and  $V_Y$  then  $R_1 = R_2$ ,  $R_{CX} = R_{CY}$  and  $R_a = R_b$ . (Note: it is acceptable to design a four quadrant multiplier and use only two quadrants of it.)

Select  $R_d$  to be 1% or 2% below (or above) the calculated value. This will cause  $\alpha$  and  $\beta$  to both be positive (or negative) by nearly the same amount. Now the effective value of  $R_d$  can be trimmed with an offset adjustment  $Z_{OS}(R_{20})$  on pin 5.

This technique causes: a slight gain error which can be compensated with the R<sub>0</sub> value, and an output of offset error that can be trimmed with Vos(R<sub>16</sub>) on the output op amp.

### **Extended Range Divider**

The only cross-product error of interest is the  $V_Z$  feedthrough ( $V_X = 0$  and  $V_{OSX} \neq 0$ ) which is easily adjusted with  $X_{OS}(R_5)$ . See Figure 6.

Resistor product mismatch will cause scaling errors (gain) that could be a problem for very low values of  $V_Z$ . Adjustments to  $Y_{OS}(R_{18})$  can be made to improve the high gain accuracy.

### **Square Root and Squaring**

These circuits are functions of single variables so feedthrough, as such, is not a consideration. Cross product errors will effect incremental accuracy that can be corrected  $Y_{OS}(R_{14})$  or  $Z_{OS}(R_{10})$ . See Figure 9 and Figure 11.

# **Appendix 2—Applications**

# **Design Considerations for RMS-to-DC Circuits**

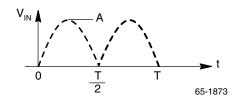

#### **Average Value**

Consider  $V_{in} = A \sin \omega \tau$ . By definition,

$$V_{AG} = \int_0^{\frac{T}{2}} V_{IN} dt$$

Where T = Period

$$\omega = 2\pi f$$
$$= \frac{2\pi}{T}$$

$$V_{AG} = \frac{2}{T} \int_{0}^{T} A \sin \omega t \, dt$$

$$= \frac{2A}{T} \left[ -\frac{1}{\omega} \cos \omega t \right]_0^{\frac{T}{2}}$$
$$= \frac{2A}{2\pi} [-\cos(\pi) + \cos(0)]$$

Average Value of Asin $\omega$ t is  $\frac{2}{\pi}$ A

### **RMS Value**

Again, consider V<sub>IN</sub> = Asinωt

$$V_{rms} = \sqrt{V_{AVG}} = \sqrt{\frac{1}{T} \int_0^T [V_{IN}]^2 dt}$$

V<sub>rms</sub> for Asinωtdt:

$$V_{rms} = \sqrt{\frac{1}{T} \int_0^T A^2 \sin^2 \omega t \, dt}$$

$$V_{rms} = \sqrt{\frac{A^2}{T}} \int_0^T \left[ \frac{1}{2} - \frac{1}{2} \cos 2 \cos 2 \omega t \right] dt$$

$$V_{rms} = \sqrt{\frac{A^2}{2} \left[ \frac{T}{2} - \frac{1}{4\omega} \sin 2 \omega t \right]_0^T}$$

$$V_{rms} = \sqrt{\frac{A^2}{2} \left[ \frac{T}{2} \right]}$$

$$V_{rms} = \sqrt{\frac{A^2}{2}}$$

Therefore, the rms value of Asinot becomes:

$$V_{rms} = \frac{A}{\sqrt{2}}$$

### **RMS Value for Rectified Sine Waves**

Consider  $V_{in} = |A| \sin \omega t|$ , a rectified wave. To solve, integrate of each half cycle.

i.e. 
$$\frac{1}{T} \int_{0}^{T} V_{in}^{2} dt =$$

$$\frac{1}{T} \left[ \int_0^{\frac{T}{2}} A^2 \sin^2 \omega t \, dt + \int_{\frac{T}{2}}^{T} (-A \sin \omega t)^2 dt \right]$$

This is the same as  $\frac{1}{1}\int_{0}^{\infty}TA^{2}\sin^{2}\omega t dt$ 

$$so, |Asin\omega t|_{rms} = Asin\omega t_{rms}$$

Practical Consideration: |Asinωt| has high-order harmonics; Asinωt does not. Therefore, non-ideal integrators may cause different errors for two approaches.

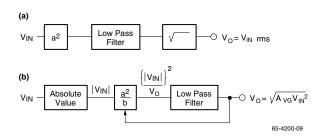

Figure 14.

$$Avg\left[\frac{V_{IN}^{2}}{V_{0}}\right] = V_{0}$$
implies  $V_{0} = \sqrt{Avg(\left|V_{IN}^{2}\right|)}$ 

$$V_{0} = \sqrt{Avg \left|V_{IN}^{2}\right|}$$

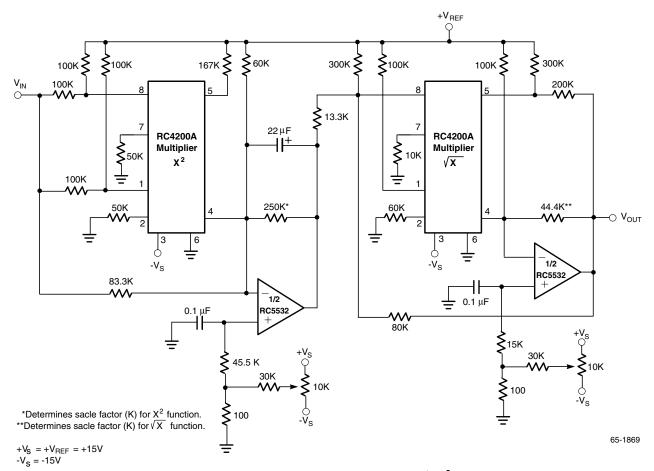

Figure 15. RMS to DC Converter Vout=√VIN<sup>2</sup>

## Amplitude Modulator with A.G.C.

In many AC modulator applications, unwanted output modulation is caused by variations in carrier input amplitude. The versatility of the RC4200 multiplier can be utilizes to eliminate this undesired fluctuation. The extended range multiplier circuit (Figure 4) shows an output amplitude inversely proportional to the reference voltage  $V_{REF}$ .

i.e., 
$$V_0 = \frac{V_X V_Y}{V_{REF}} \frac{R_0 R_d}{R_1 R_2}$$

By making  $V_{REF}$  proportional to  $V_Y$  (where  $V_Y$  is the carrier input) such that:

$$V_{REF} = V_{H} = \int (|V_{Y}|)$$

Then the denominator becomes a variable value that automatically provides constant gain, such that the modulating input  $(V_X)$  modulates the carrier  $(V_Y)$  with a fixed scale factor even though the carrier varies in amplitude.

If V<sub>H</sub> is made proportional to the average value of Asin $\omega$ t (i.e.,  $2A/\pi$ ) and scaled by a value of  $\pi/2$  then:

V<sub>H</sub>=A

and if: VX = Modulating input (VM)

and: Vy Carrier input (Asinot)

Then: 
$$V_0 = K V_M \text{ sin}\omega t \text{ where } K = \frac{R_0 R_d}{R_1 R_2}$$

The resistor scaling is determined by the dynamic range of the carrier variation and modulating input.

The resistor values are solved, as with the other extended range circuits, in terms of the input voltages.

Input voltages:

Modulation voltage (V<sub>M</sub>):  $0 \le V_M \le V_X(max.)$ 

Carrier  $(V_Y)$ :  $V_Y = A \sin \omega t$ 

Carrier amplitude fluctuation ( $\Delta A$ ):

 $A(\min.) \sin t \le V_Y \le A(\max.) \sin \Omega \omega t$ 

Dynamic Range (N): A(max.)/A(min.),

 $A(max.) = V_H(max.)$  and  $A(min.) = V_H(min.)$ 

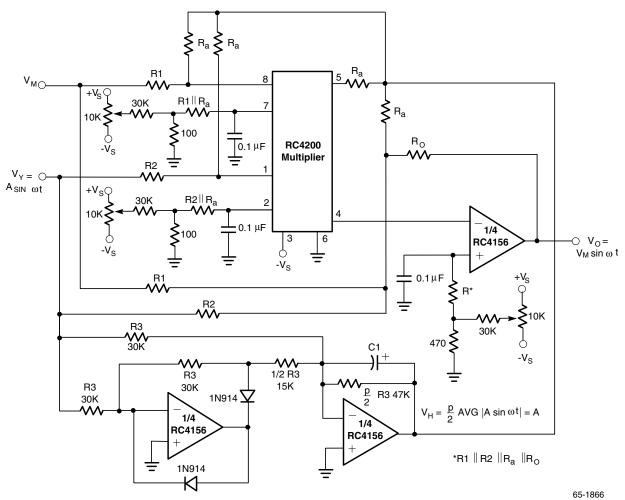

Figure 16. Amplitude Modulator with A.G.C.

The maximum and minimum values for I1 and I2 lead to:

$$\begin{split} &I_{1}(\text{max.}) = \frac{V_{X}(\text{max.})}{R_{1}} + \frac{V_{H}(\text{max.})}{R_{a}} = 250 \mu A \\ &I_{1}(\text{min.}) = \frac{V_{H}(\text{min.})}{R_{a}} = 50 \mu A V_{M}(\text{min.}) = 0 \\ &I_{2}(\text{max.}) = \frac{A(\text{max.})}{R_{2}} + \frac{V_{H}(\text{max.})}{R_{a}} = 250 \mu A \\ &I_{2}(\text{min.}) = \frac{V_{H}(\text{min.})}{R_{a}} = 50 \mu A \end{split}$$

For a dynamic range of N, where

$$N = \frac{A(\text{max.})}{A(\text{min.})} < 5,$$

These equations combine to yield:

$$\begin{split} R_1 &= \frac{V_X(\text{max.})}{(5-N)50\mu\text{A}}, \ R2\frac{A(\text{max.})}{(5-N)50\mu\text{A}}, \\ R_a &= \frac{A(\text{min.})}{50\mu\text{A}} \ \text{and} \ R_O = K \ \frac{R_1R_2}{R_a}, \end{split}$$

#### Example

VY = Asin $\omega$ t 2.5V  $\leq$  A  $\leq$  10V, therefore N = 4 0V  $\leq$  V<sub>M</sub>  $\leq$  10V, therefore V<sub>X</sub>(max.) = 10V K = 1, therefore V<sub>0</sub> = V<sub>M</sub> sin $\omega$ t

$$R_{1} = \frac{V_{X}(\text{max.})}{50\mu A} = \frac{10V}{50\mu A} = 200K$$

$$R_{1} = \frac{A(\text{max.})}{50\mu A} = \frac{10V}{50\mu A} = 200K$$

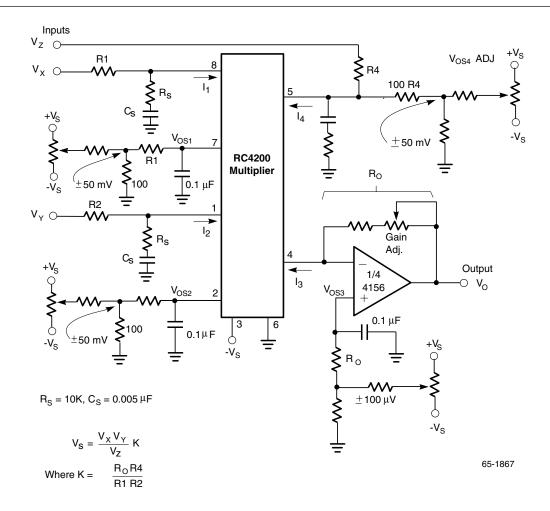

$$R_{a} = \frac{A(\text{min.})}{50\mu A} = \frac{2.5V}{50\mu A} = 50K$$

$$R_{O} = K\frac{R_{1}R_{2}}{R_{a}} = 1\frac{200K \times 200K}{50K} = 800K$$

#### Example 2

$$\begin{split} &V_Y = Asin\omega t \ 3 \le A \le 6, \ therefore \ N=2 \\ &0V \le V_M \le 8V, \ therefore \ V_X(max.) = 8V \\ &K=0.2, \ therefore \ V_0=0.2 \ V_M \ sinwt \\ &so: \\ &R_1=53.3K, \ R_2=40K \end{split}$$

$$R_1 = 53.3K$$
,  $R_2 = 40K$   
 $R_a = 60K$  and  $R_0 = 7.11K$ 

### **Limited Range, First Quadrant Applications**

The following circuit has the advantage that cross-product errors are due only to input offsets and nonlinearity error is sightly error is slightly less for lower input currents.

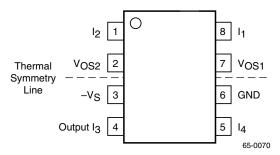

The circuit also has no standby current to add to the noise content, although the signal-to-noise ratio worsens at very low input currents (1-5  $\mu A$ ) due to the noise current of the input stages.

The RsCs filter circuits are added to each input to improve the stability for input currents below 50  $\mu A$ .

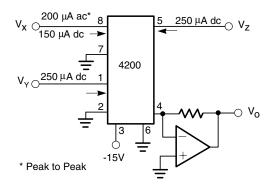

### Caution!

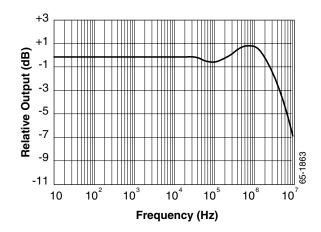

The bandpass drops off significantly for lower currents (<50  $\mu A)$  and non-symmetrical rise and fall times can cause second harmonic distortion.

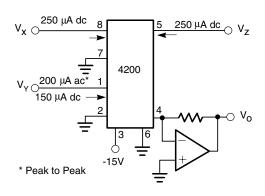

## **Thermal Symmetry**

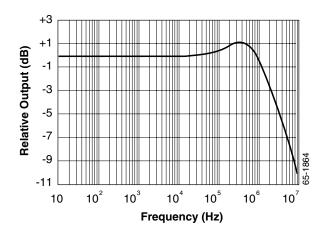

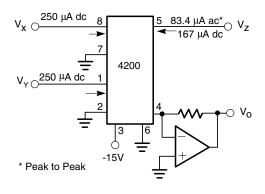

The scale factor is sensitive to temperature gradients across the chip in the lateral direction. Where possible, the package should be oriented such that forces generating temperature gradients are located physically on the line of thermal symmetry. This will minimize scale-factor error due to thermal gradients.
