1 PRODUCT OVERVIEW

SAM8 PRODUCT FAMILY

Samsung's SAM8 family of 8-bit single-chip CMOS microcontrollers offers a fast and efficient CPU with a wide range of integrated peripherals, in various mask-programmable ROM sizes. Analog its major CPU features are:

— Efficient register-oriented architecture

— Selectable CPU clock sources

— Idle and Stop power-down mode release by interrupt

— Built-in basic timer with watchdog function

The sophisticated interrupt structure recognizes up to eight interrupt levels. Each level can have one or more interrupt sources and vectors. Fast interrupt processing (within a minimum of four CPU clocks) can be assigned to specific interrupt levels.

S3C8639/C863A/P863A MICROCONTROLLERS

S3C8639/C863A/P863A single-chip 8-bit microcontrollers are based on the powerful SAM8 CPU architecture. The internal register file is logically expanded to increase the on-chip register space. S3C8639/C863A/P863A contain 32/48 Kbytes of on-chip program ROM.

In line with Samsung's modular design approach, the following peripherals are integrated with the SAM8 core:

— Four programmable I/O ports (total 27 pins)

— One 8-bit basic timer for oscillation stabilization and watchdog functions

— One 8-bit general-purpose timer/counter with selectable clock sources

— One interval timer

— One 12-bit counter with selectable clock sources, including Hsync or Csync input

— PWM block with seven 8-bit PWM circuits

— Sync processor block (for Vsync and Hsync I/O, Csync input, and Clamp signal output)

— DDC Multi-master and slave-only IIC-Bus

— 4-channel A/D converter (8-bit resolution)

S3C8639/C863A/P863A are a versatile microcontrollers which are ideal for use in multi-sync monitors or in general-purpose applications that require sophisticated timer/counter, PWM, sync signal processing, A/D converter, and multi-master IIC-bus support with DDC. They are available in a 42-pin SDIP or a 44-pin QFP package.

OTP

S3C8639/C863A microcontrollers are also available in OTP (One Time Programmable) version named, S3P863A. S3P863A microcontroller has an on-chip 48-Kbyte one-time-programmable EPROM instead of masked ROM. S3P863A is comparable to S3C8639/C863A, both in function and pin configuration except its ROM size.

SAMSUNG
ELECTRONICS

S3C8647/F8647 MICROCONTROLLERS

S3C8647/F8647 single-chip 8-bit microcontrollers are based on the powerful SAM8 CPU architecture. The internal register file is logically expanded to increase the on-chip register space.
S3C8647/F8647 contain 24 Kbytes of on-chip program ROM.

In line with Samsung's modular design approach, the following peripherals are integrated with the SAM8 core:

— Three programmable I/O ports (total 19 pins)

— One 8-bit basic timer for oscillation stabilization and watchdog functions

— One 8-bit general-purpose timer/counter with selectable clock sources

— One interval timer

— One 12-bit counter with selectable clock sources, including Hsync or Csync input

— PWM block with six 8-bit PWM circuits

— Sync processor block (for Vsync and Hsync I/O, Csync input, and Clamp signal output)

— DDC Multi-master IIC-Bus

— 4-channel A/D converter (4-bit resolution)

S3C8647/F8647 are a versatile microcontrollers which are ideal for use in multi-sync monitors or in general-purpose applications that require sophisticated timer/counter, PWM, sync signal processing, A/D converter, and multi-master IIC-bus support with DDC. They are available in a 32-pin SDIP/SOP package.

FLASH

S3C8647 microcontroller is also available in Flash version named, S3F8647. S3F8647 microcontroller has an on-chip 24-Kbyte flash cells instead of masked ROM. S3F8647 is comparable to S3C8647, both in function and pin configuration.

SAMSUNG
ELECTRONICS

FEATURES

CPU

- SAM88RC CPU core

Memory

- S3C8639: 32-Kbyte program memory (ROM)
  S3C863A: 48-Kbyte program memory (ROM)
  S3C8647: 24-Kbyte program memory (ROM)

- S3C8639: 784-byte general-purpose
          register area
  S3C863A: 1040-byte general-purpose
          register area
  S3C8647: 400-byte general-purpose
          register area

Instruction Set

- 78 instructions

- IDLE and STOP instructions added for
  power-down modes

Instruction Execution Time

- Minimum 333 ns (with 12 MHz CPU clock)

Interrupts

- Ten (nine)* interrupt sources/vectors (S3C8647)*

- Eight (seven)* interrupt level (S3C8647)*

- Fast interrupt feature

General I/O

- S3C863X: four I/O ports (total 27pins)
  S3C8647: three I/O ports (total 19pins)

8-Bit Basic Timer

- Programmable timer for oscillation stabilization
  interval control or watchdog timer function

- Three selective internal clock frequencies

Timer/Counters

- One 8-bit Timer/Counter with several clock
  sources (Capture mode)

- One 12-bit Counter with H-/C-sync and several
  clock sources

- One Interval Timer

Low Voltage Detector (LVD & POR)

Pulse Width Modulator (PWM)

- 8-bit PWM: 7(6)*-Ch (S3C8647)*
  (6-bit basic frame with 2-bit extension)

Sync-Processor Block

- Vsync-I, Hsync-I, Csync-I input and Vsync-O,
  Hsync-O, Clamp-O output pins

- Programmable Pseudo sync signal generation

- Auto SOG detection

- Auto H-/V-sync polarity detection

- Composite sync detection

DDC Multi-Master IIC-Bus 1-Ch

- Serial Peripheral Interface

- Support for Display Data Channel
  (DDC1/DDC2B/DDC2Bi/DDC2B+)

Slave Only IIC-Bus 1-Ch (Only S3C863X)

- Serial Peripheral Interface

A/D Converter

- 4-channel; 8(4)*-bit resolution (S3C8647)*

Oscillator Frequency

- 8 MHz to 12 MHz crystal operation

- Internal Max. 12 MHz CPU clock

Operating Temperature Range

- $-40\ °C$ to $+85\ °C$

Operating Voltage Range

- 3.0(4.0)* V to 5.5 V (S3C8647)*

Package Types

- S3C863X: 42-pin SDIP, 44-pin QFP
 S3C8647: 32-pin SDIP, 32-pin SOP

NOTES

2 ADDRESS SPACES

OVERVIEW

S3C8639/C863A/C8647 microcontrollers have two types of address space:

— Internal program memory (ROM)

— Internal register file

The 16-bit address and data bus support program memory operations. The separate 8-bit register bus carries addresses and data between the CPU and the internal register file. S3C8639/C863A/C8647 employ an internal 32/48/24-Kbyte mask-programmable ROM. External memory interface is not implemented.

There are 852/1108/462 8-bit registers in the internal register file. In this space, there are 784/1040/400 registers for general use, 19 for CPU and system control, and 49(43) for peripheral control and data. An area of 16-byte common working register (scratch) is part of the general-purpose register space. Most of these registers serve as either a source or destination address, or as accumulators for data memory operations.

PROGRAM MEMORY (ROM)

Program memory (ROM) stores program code or table data. S3C8639/C863A employ 32/48-Kbytes of mask-programmable program memory. The memory address range is 0H–7FFFH/BFFFH (see Figure 2-1).

S3C8647 employs 24-Kbytes of mask-programmable program memory.
The memory address large is 0H-5FFFH.

The first 256 bytes of the ROM (0H–FFH) are reserved for interrupt vector addresses. Unoccupied locations in the address range can be used as normal program memory. When you use the vector address area to store program code, be careful not to overwrite vector addresses stored in these locations.

The ROM address at which program execution starts after a reset is 0100H.
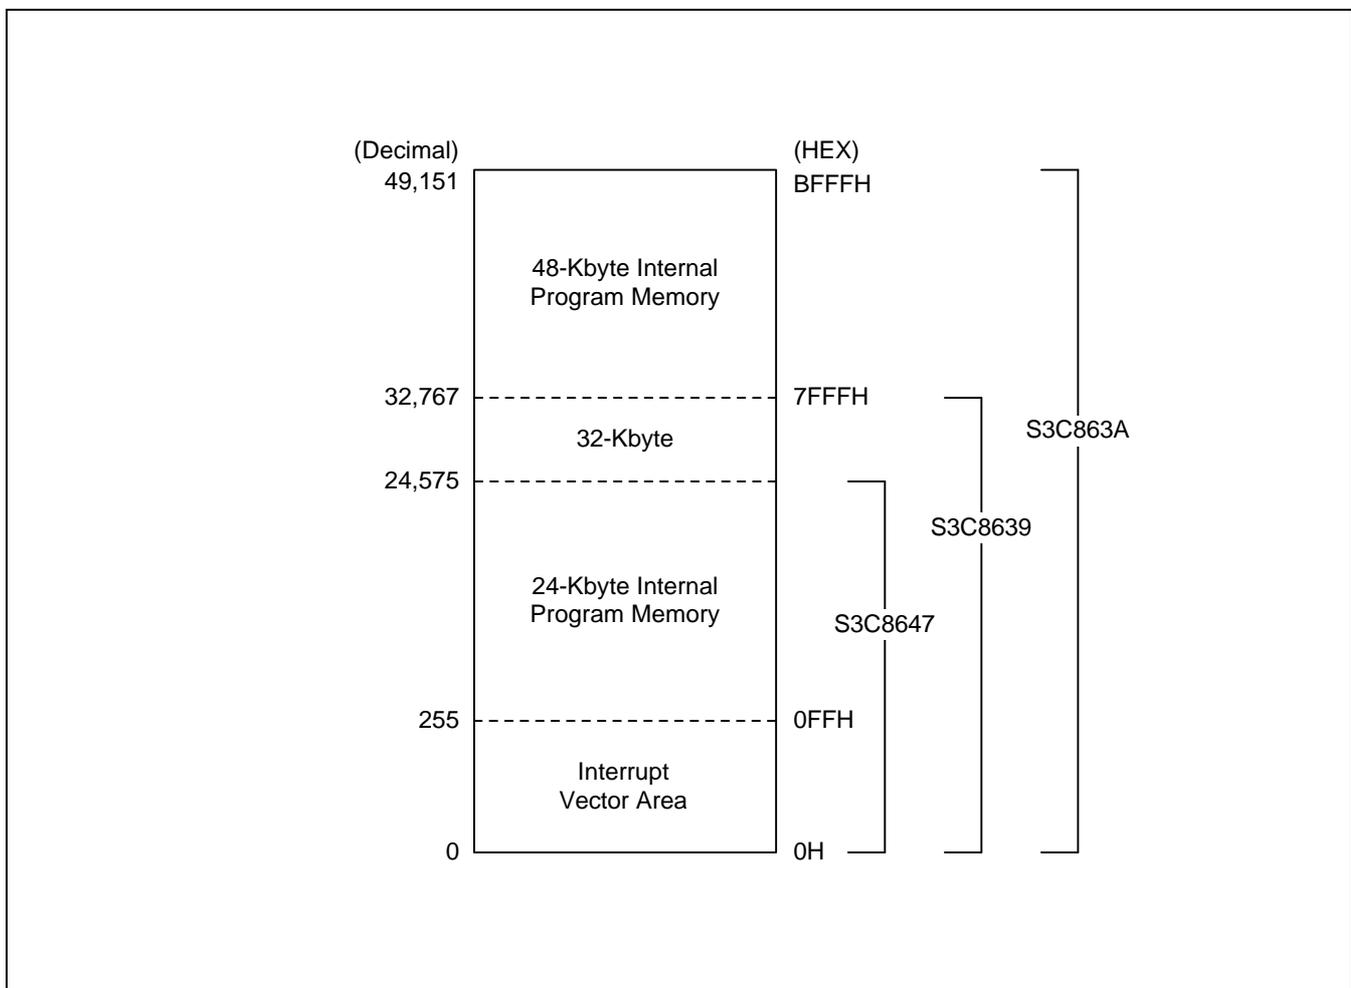

Figure 2-1. Program Memory Address Space

REGISTER ARCHITECTURE

The upper 64-byte area of the S3C8639/C863A/C8647 files is logically expanded to two 64-byte areas, called *set 1* and *set 2*. The upper 32-byte area of set 1 is divided into two register banks, *bank 0* and *bank 1*. The total physical register space is thereby expanded internal register to 864/1120 bytes. Within this physical space, there are 864/1120/462-byte registers, of which 852/1108/450 are addressable.

Given the microcontroller's 8-bit register bus architecture, up to 256 bytes of physical register space can be addressed as a single page. The S3C8639 register files have three pages, page 0, page 1 and page 2. And the S3C863A register files have four pages, page 0, page 1, page 2 and page 3. The S3C8647 register files have two pages, page 0, and page 1. All page contain 256 bytes respectively.

The extension of physical register space into separately addressable areas (sets, banks, and pages) is enabled by addressing mode restrictions, the select bank instructions SB0 and SB1, and the register page pointer, PP.

Specific register types and areas (in bytes) they occupy in the S3C8639/C863A/C8647 internal register files are summarized in Table 2-1.

Table 2-1. Register Type Summary

Register Type	Number of Bytes (S3C8639/C863A)	Number of Bytes (S3C8647)
General-purpose registers (including the 16-byte common working register area)	784/1040	400
CPU and system control registers	19	19
Clock, peripheral, I/O control, and data registers	49	43
Total Addressable Bytes	852/1108	462

REGISTER PAGE POINTER (PP)

The SAM8 architecture supports the logical expansion of the physical 256-byte internal register file (which use an 8-bit data bus) to as many as 16 separately addressable register pages. Page addressing is controlled by the register page pointer (PP, DFH). Two logical pages are implemented in S3C8639/C863A/C8647. These pages are used as general purpose register space.

Register Page Pointer (PP)

1 1 1 1 B	Not used for the S3C8639/C863A/C8647

Figure 2-4. Register Page Pointer (PP)

REGISTER SET 1

The term *set 1* refers to the upper 64 bytes of the register file, locations C0H–FFH. The upper 32-byte area of this 64-byte space (E0H–FFH) is divided into two 32-byte register banks, *bank 0* and *bank 1*. You execute the set register bank instructions SB0 or SB1 to address one bank or the other. Bank 0 is automatically selected by a reset operation.

In S3C8639/C863A, register locations of only E0H–F4H are addressable in the bank 1 area; the remaining locations (F5H–FFH) are not mapped. The lower 32-byte area of set 1 is not banked and can be addressed at any time. It contains 16 mapped system registers (D0H–DFH) and a 16-byte "scratch" area (C0H–CFH) for working register addressing.

Registers in set 1 are directly accessible at all times using Register addressing mode. The 16-byte working register area can only be accessed using working register addressing. (For more information about working register addressing, please refer to Chapter 3, "Addressing Modes.")

REGISTER SET 2

The same 64-byte physical space that is used for set 1 register locations C0H–FFH is logically duplicated to add another 64 bytes of space. This expanded area of the register file is called *set 2*. All set 2 locations (C0H–FFH) can be addressed in all page of the S3C8639/C863A register space.

The logical division of set 1 and set 2 is maintained by means of addressing mode. In order to access set 1, you should use resister addressing mode. When you want to access register locations in set 2, you have to select Register Indirect addressing mode or Indexed addressing mode access register locations in set 2.

SAMSUNG
ELECTRONICS

PRIME REGISTER SPACE

The lower 192 bytes of the 256-byte physical internal register file (00H–BFH) is called the *prime register space,* or more simply, the *prime area*. You can access registers in this address range at all page using any of the seven explicit addressing modes (see chapter 3, "Addressing Modes"). All registers in the prime area can be addressed immediately after a reset.

Figure 2-5. Set 1, Set 2, and Prime Area Register Map (S3C863X)

Figure 2-6. Set 1, Set 2, and Prime Area Register Map (S3C8647)

WORKING REGISTERS

Instructions can access specific 8-bit registers or 16-bit register pairs using either 4-bit or 8-bit address fields. When 4-bit working register addressing is used, the 256-byte register file can be seen by the programmer as one that consists of 32 8-byte register groups or "slices." Each slice comprises of eight 8-bit registers.

With the two 8-bit register pointers, RP1 and RP0 employed, two working register slices can be selected at any time to form a 16-byte working register block. The register pointers help, you move this 16-byte register block to anywhere in the addressable register file, except for the set 2 area.

The terms *slice* and *block* are used in this manual to help you visualize the size and relative locations of selected working register spaces:

— One working register *slice* is 8 bytes (eight 8-bit working registers; R0–R7 or R8–R15)

— One working register *block* is 16 bytes (sixteen 8-bit working registers; R0–R15)

All the registers in an 8-byte working register slice have the same binary value for their five most significant address bits. This makes it possible for each register pointer to point to one of the 24 slices in the register file. The base addresses for the two 8-byte register slices selected are contained in register pointers RP0 and RP1.

After a reset, RP0 and RP1 always point to the 16-byte common area in set 1 (C0H–CFH).
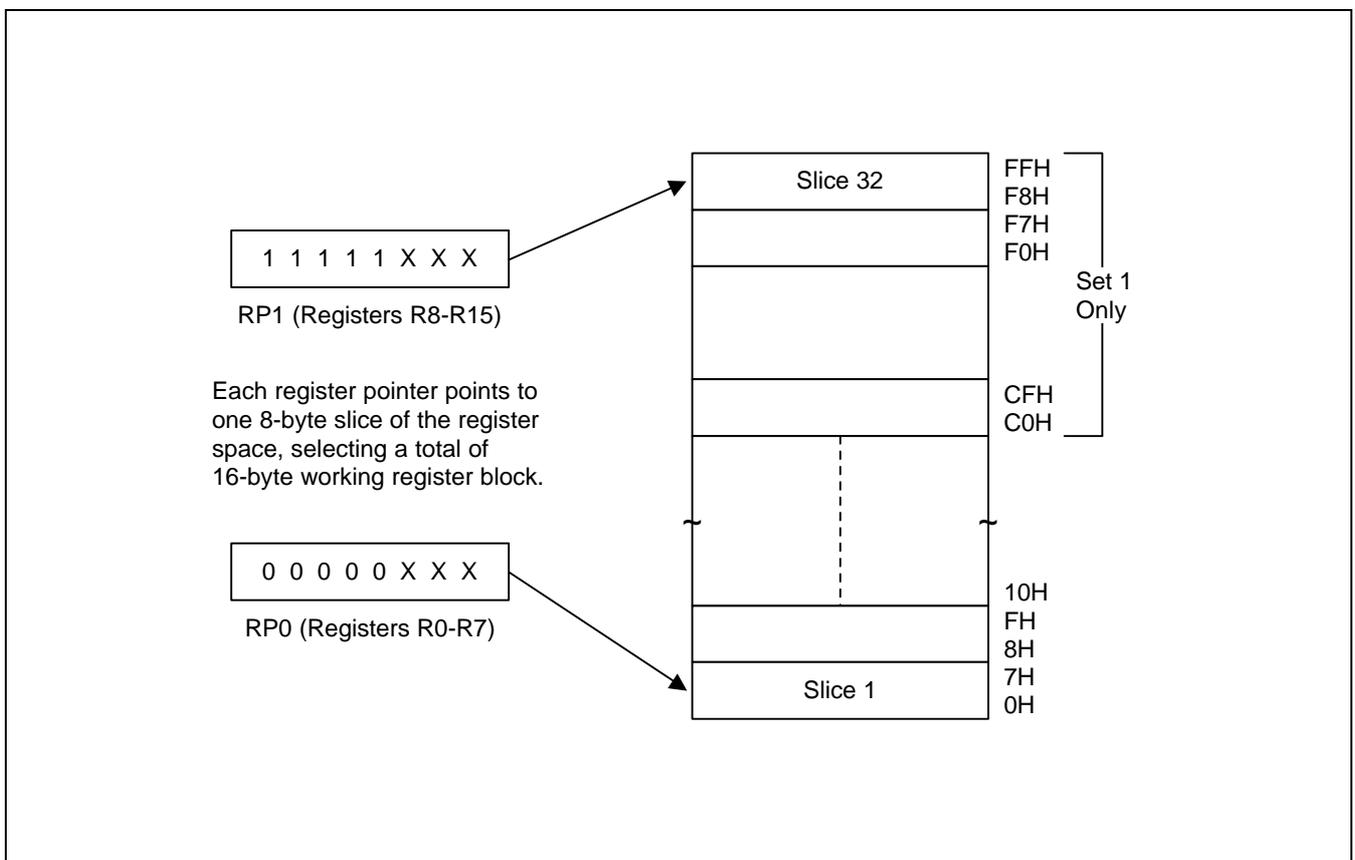

Figure 2-7. 8-Byte Working Register Areas (Slices)

USING THE REGISTER POINTERS

Register pointers of RP0 and RP1 which are mapped to the addresses D6H and D7H in set 1, are used to select two movable 8-byte working register slices in the register file. After a reset, they point to the working register common area: RP0 points to the addresses C0H–C7H, and RP1 points to the addresses C8H–CFH.

You can change a register pointer value, by loading a new value to RP0 and/or RP1 using an SRP or LD instruction (see Figures 2-6 and 2-7).

In working register addressing, you can only access those two 8-bit slices of the register file that are currently pointed to by RP0 and RP1. You cannot use the register pointers to select a working register area in set 2, C0H–FFH, because these locations can be accessed only with Indirect Register or Indexed addressing modes.

The 16-byte working register block selected usually consists of two contiguous 8-byte slices. As a general programming guideline, we recommend that RP0 point to the "lower" slice and RP1 point to the "upper" slice (see Figure 2-6). In some cases, it may be necessary to define working register areas in different (non-contiguous) areas of the register file. In Figure 2-7, RP0 points to the "upper" slice and RP1 to the "lower" slice.

As a register pointer can point to either of the two 8-byte slices in the working register block, you can flexibly define the working register area to support a variety of program requirements.

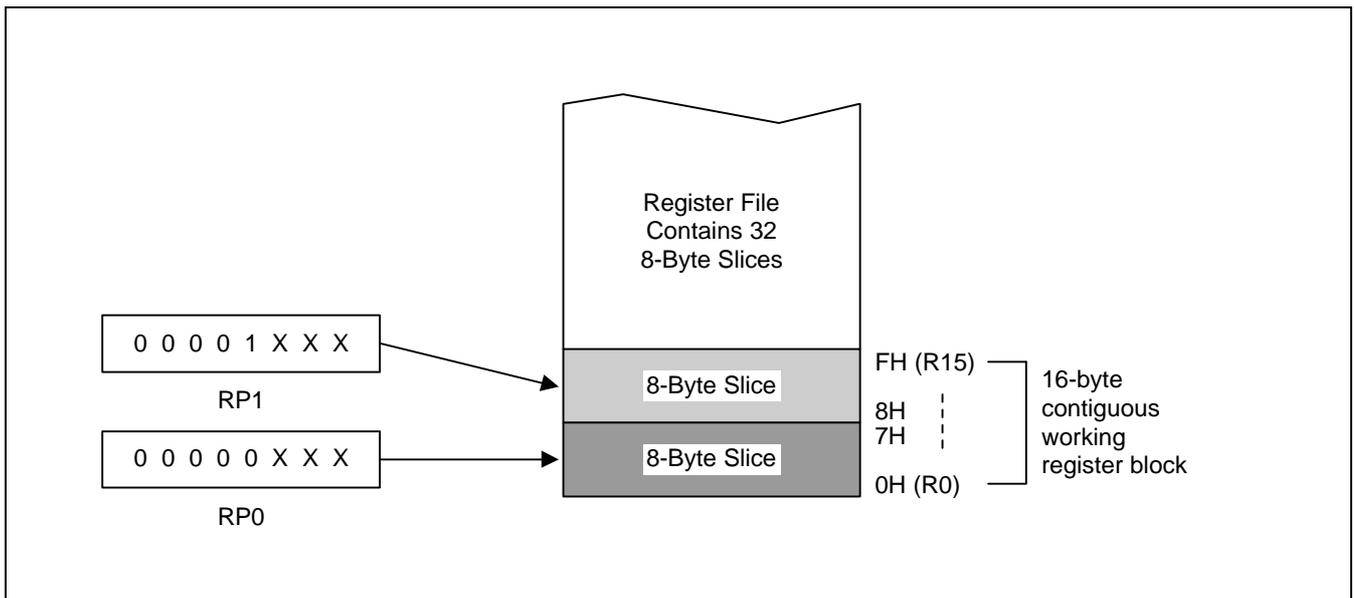

Figure 2-8. Contiguous 16-Byte Working Register Block
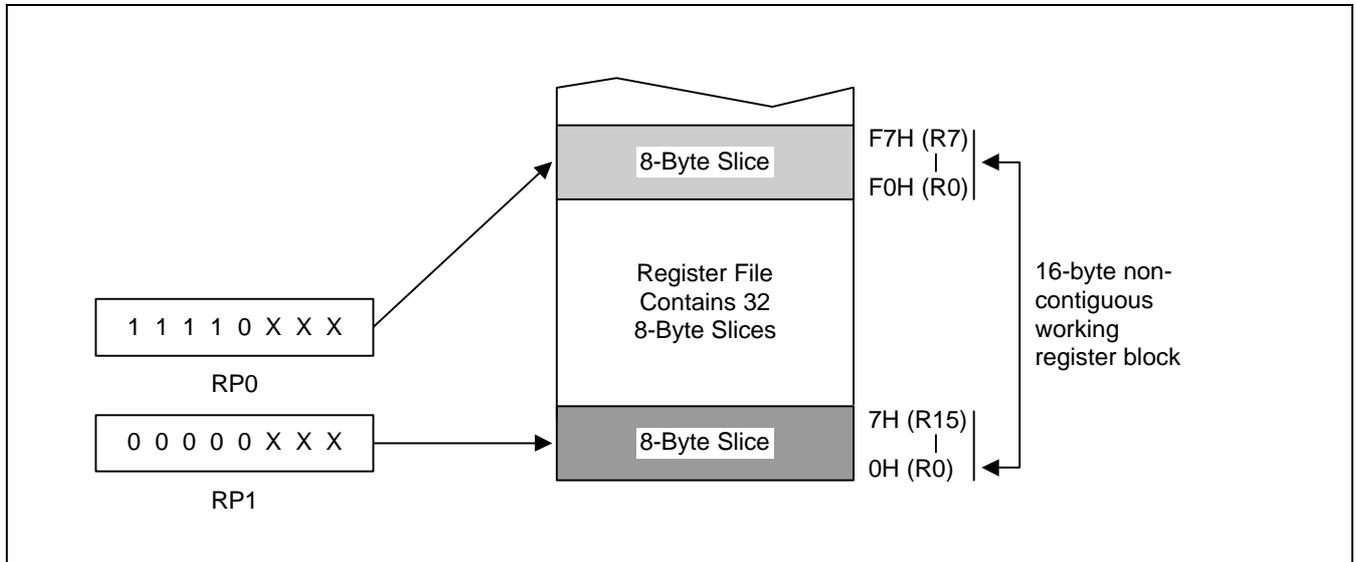

Figure 2-9. Non-Contiguous 16-Byte Working Register Block

☞ **PROGRAMMING TIP — Calculate the Sum of a Series of Registers Using the RPs**

Calculate the sum of registers 80H–85H using the register pointer and working register addressing. The register addresses from 80H through 85H contain the values 10H, 11H, 12H, 13H, 14H, and 15H, respectively:

```
SRP0        #80H                ;  RP0 ← 80H
ADD         R0,R1               ;  R0 ← R0 + R1
ADC         R0,R2               ;  R0 ← R0 + R2 + C
ADC         R0,R3               ;  R0 ← R0 + R3 + C
ADC         R0,R4               ;  R0 ← R0 + R4 + C
ADC         R0,R5               ;  R0 ← R0 + R5 + C
```

The sum of these six registers, 6FH, is located in the register R0 (80H). The instruction string used in this example takes 12 bytes of instruction code and its execution time is 24 cycles. If the register pointer is not used to calculate the sum of these registers, the following instruction sequence would have to be used:

```
ADD         80H,81H             ;  80H ← (80H) + (81H)
ADC         80H,82H             ;  80H ← (80H) + (82H) + C
ADC         80H,83H             ;  80H ← (80H) + (83H) + C
ADC         80H,84H             ;  80H ← (80H) + (84H) + C
ADC         80H,85H             ;  80H ← (80H) + (85H) + C
```

The sum of the six registers, here, is also located in the register 80H. This instruction string, however, takes 15 bytes of instruction code instead of 12 bytes, and its execution time is 30 cycles instead of 24 cycles.

REGISTER ADDRESSING

The SAM8 register architecture provides an efficient method of working register addressing that takes full advantage of shorter instruction formats to reduce execution time.

With Register (R) addressing mode, in which the operand value is the content of a specific register or register pair, you can access all locations in the register file except for set 2. With working register addressing, you use a register pointer to specify an 8-byte working register space in the register file and an 8-bit register within that space.

Registers are addressed either as a single 8-bit register or as a paired 16-bit register space. In a 16-bit register pair, the address of the first 8-bit register is always an even number and the address of the next register is always an odd number. The most significant byte of the 16-bit data is always stored in the even-numbered register; the least significant byte is always stored in the next (+1) odd-numbered register.

Working register addressing differs from Register addressing in a way that it uses a register pointer to specify an 8-byte working register space in the register file and an 8-bit register within that space (see Figure 3-2).

Figure 2-11. Register File Addressing

COMMON WORKING REGISTER AREA (C0H–CFH)

After a reset, register pointers RP0 and RP1 automatically select two 8-byte register slices in set 1, locations C0H–CFH, as the active 16-byte working register block:

RP0 $\rightarrow$ C0H–C7H
RP1 $\rightarrow$ C8H–CFH

This16-byte address range is called *common working register area*. That is, locations in this area can be used as working registers by operations that address any location on any page in the register file. Typically, these working registers serve as temporary buffers for data operations between different pages.

☞ **PROGRAMMING TIP — Addressing the Common Working Register Area**

As the following examples show, you should access working registers in the common area, locations C0H–CFH, using working register addressing mode only.

Examples: 1. LD   0C2H,40H   ; Invalid addressing mode!

                      Use working register addressing instead:

                      SRP   #0C0H

                      LD   R2,40H   ; R2 (C2H) ← the value in location 40H

    2. ADD   0C3H,#45H   ; Invalid addressing mode!

                      Use working register addressing instead:

                      SRP   #0C0H

                      ADD   R3,#45H   ; R3 (C3H) ← R3 + 45H

4-BIT WORKING REGISTER ADDRESSING

Each register pointer defines a movable 8-byte slice of working register space. The address information stored in a register pointer serves as an addressing "window" that makes it possible for instructions to access working registers very efficiently using short 4-bit addresses. When an instruction addresses a location in the selected working register area, the address bits are concatenated in the following way to form a complete 8-bit address:

— The high-order bit of the 4-bit address selects one of the register pointers ("0" selects RP0; "1" selects RP1);

— The five high-order bits in the register pointer select an 8-byte slice of the register space;

— The three low-order bits of the 4-bit address select one of the eight registers in the slice.

As shown in Figure 2-11, the result of this operation is that the five high-order bits from the register pointer are concatenated with the three low-order bits from the instruction address to form the complete address. As long as the address stored in the register pointer remains unchanged, the three bits from the address will always point to an address in the same 8-byte register slice.

Figure 2-12 shows a typical example of 4-bit working register addressing: the high-order bit of the instruction "INC R6" is "0", which selects RP0. The five high-order bits stored in RP0 (01110B) are concatenated with the three low-order bits of the instruction's 4-bit address (110B) to produce the register address 76H (01110110B).
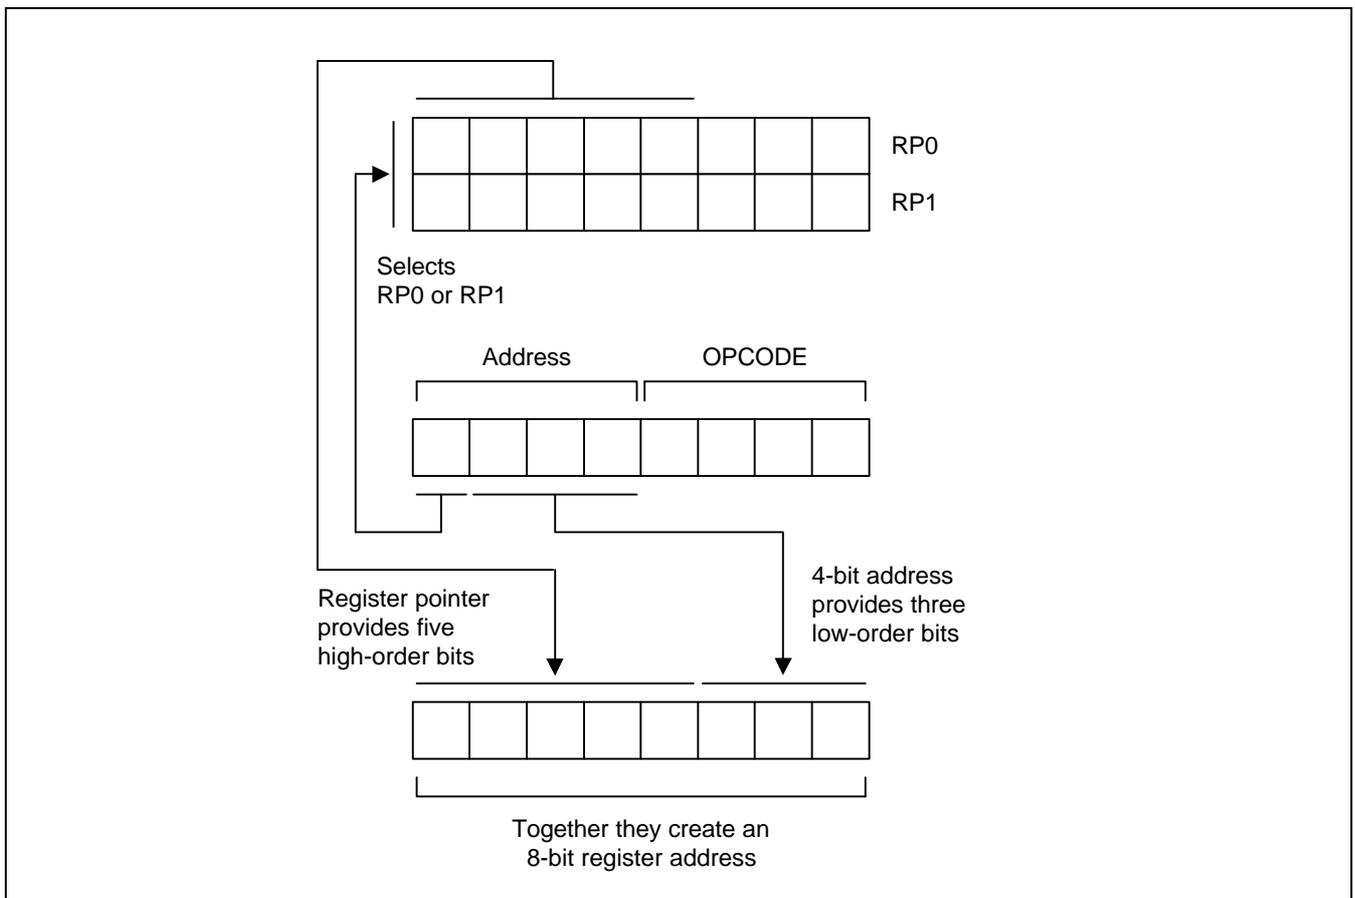

Figure 2-14. 4-Bit Working Register Addressing
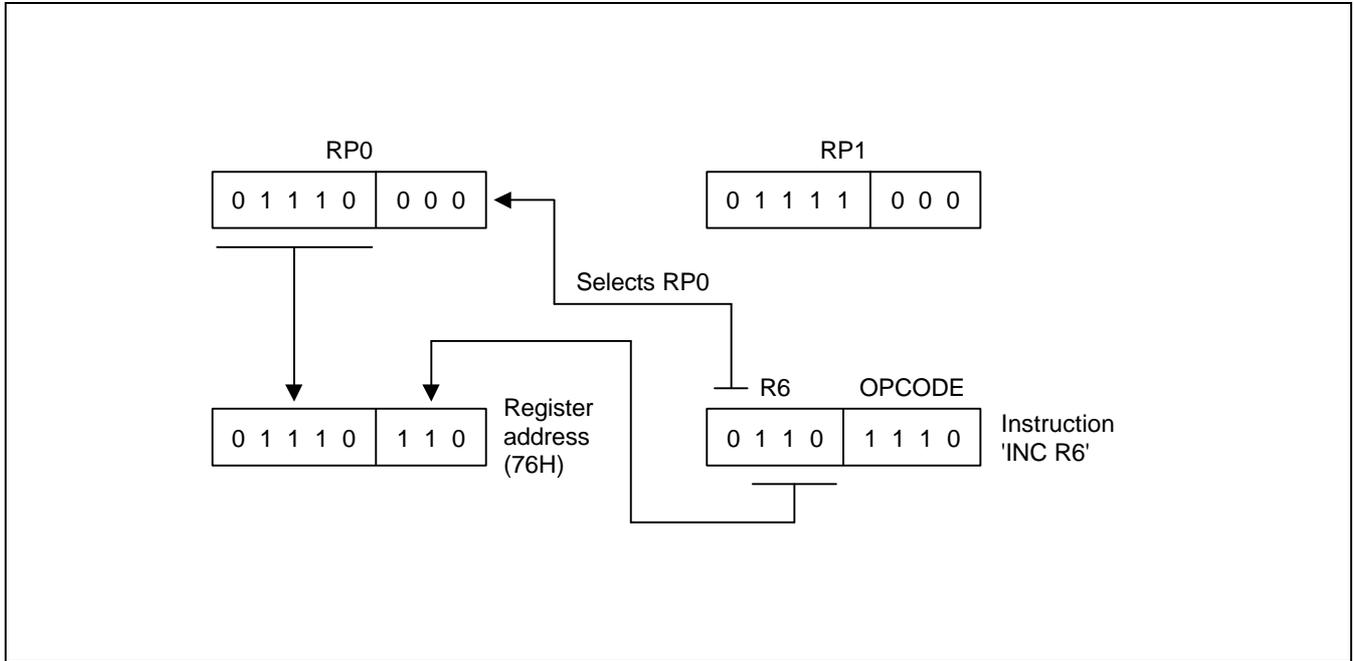

Figure 2-15. 4-Bit Working Register Addressing Example

8-BIT WORKING REGISTER ADDRESSING

You can also use 8-bit working register addressing to access registers in a selected working register area. To initiate 8-bit working register addressing, the upper four bits of the instruction address must contain the value of 1100B. This 4-bit value (1100B) indicates that the remaining four bits have the same effect as 4-bit working register addressing.

As shown in Figure 2-13, the lower nibble of the 8-bit address is concatenated in much the same way as for 4-bit addressing: Bit 3 selects either RP0 or RP1, which then supplies the five high-order bits of the final address; the three low-order bits of the complete address are provided by the original instruction.

Figure 2-14 shows an example of 8-bit working register addressing: the four high-order bits of the instruction address (1100B) specify 8-bit working register addressing. Bit 4 ("1") selects RP1 and the five high-order bits in RP1 (10101B) become the five high-order bits of the register address. The three low-order bits of the register address (011) are provided by the three low-order bits of the 8-bit instruction address. The five address bits from RP1 and the three address bits from the instruction are concatenated to form the complete register address, 0ABH (10101011B).

SYSTEM AND USER STACKS

S3-series microcontrollers can be programmed to use the system stack for subroutine calls, returns and interrupts and to store data. The PUSH and POP instructions are used to control system stack operations. The S3C8639/C863A architecture supports stack operations in the internal register file.

Stack Operations

Return addresses for procedure calls and interrupts and data are stored on the stack. The contents of the PC are saved to stack by a CALL instruction and restored by the RET instruction. When an interrupt occurs, the contents of the PC and the FLAGS register are pushed to the stack. The IRET instruction then pops these values back to their original locations. The stack address is always decremented *before* a push operation and incremented *after* a pop operation. The stack pointer (SP) always points to the stack frame stored on the top of the stack, as shown in Figure 2-15.
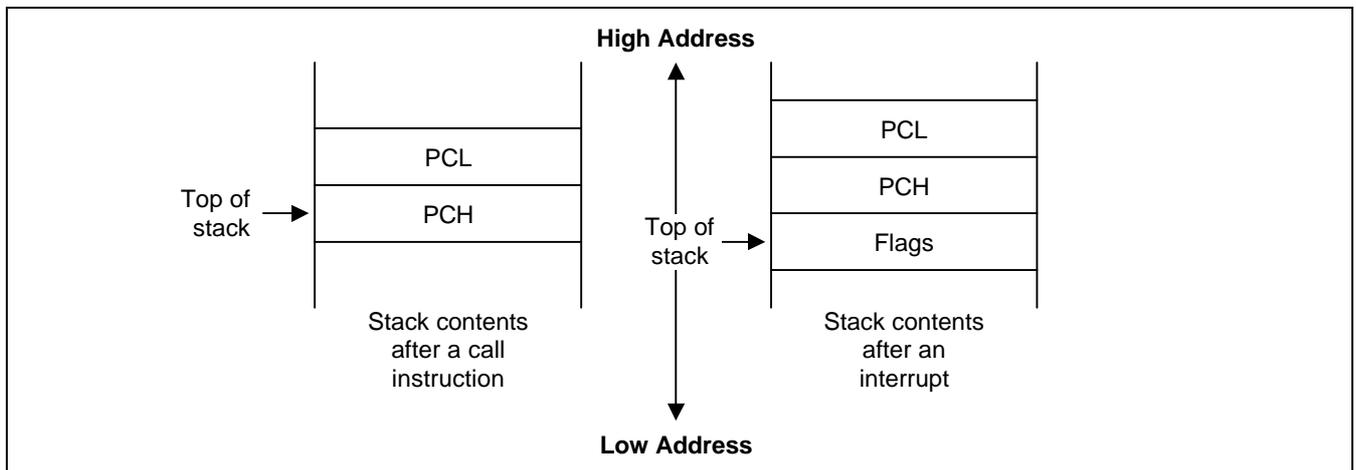

Figure 2-18. Stack Operations

User-Defined Stacks

You can freely define stacks in the internal register file as data storage locations. The instructions PUSHUI, PUSHUD, POPUI, and POPUD support user-defined stack operations.

Stack Pointers (SPL, SPH)

Register locations D8H and D9H contain the 16-bit stack pointer (SP) that is used for system stack operations. The most significant byte of the SP address, SP15–SP8, is stored in the SPH register (D8H) and the least significant byte, SP7–SP0, is stored in the SPL register (D9H). After a reset, the SP value is undetermined.

Because only internal memory space is implemented in S3C8639/C863A, the SPL must be initialized to an 8-bit value in the range 00H–FFH. The SPH register is not needed here and can be used as a general-purpose register, if necessary.

When the SPL register contains the only stack pointer value (that is, when it points to a system stack in the register file), you can use the SPH register as a general-purpose data register. However, if an overflow or underflow condition occurs as the result of incrementing or decrementing the stack address in the SPL register during normal stack operations, the value in the SPL register will overflow (or underflow) to the SPH register, overwriting any data that is currently stored there. To avoid overwriting data in the SPH register, you can initialize the SPL value to "FFH" rather than "00H".

☞   PROGRAMMING TIP — Standard Stack Operations Using PUSH and POP

The following example shows you how to perform stack operations in the internal register file using PUSH and POP instructions:

```
        LD          SPL,#0FFH              ;  SPL  ←  FFH
                                           ;  (Normally, the SPL is set to 0FFH by the initialization
                                           ;  routine)
        •
        •
        •
        PUSH        PP                     ;  Stack address 0FEH  ←  PP
        PUSH        RP0                    ;  Stack address 0FDH  ←  RP0
        PUSH        RP1                    ;  Stack address 0FCH  ←  RP1
        PUSH        R3                     ;  Stack address 0FBH  ←  R3
        •
        •
        •
        POP         R3                     ;  R3  ←  Stack address 0FBH
        POP         RP1                    ;  RP1  ←  Stack address 0FCH
        POP         RP0                    ;  RP0  ←  Stack address 0FDH
        POP         PP                     ;  PP  ←  Stack address 0FEH
```

SAMSUNG
ELECTRONICS

3   ADDRESSING MODES

OVERVIEW

The program counter is used to fetch instructions that are stored in program memory for execution. Instructions indicate the operation to be performed and the data to be operated on. *Addressing mode* is used to determine the location of the data operand. The operands specified in SAM8 instructions may be condition codes, immediate data, or a location in the register file, program memory, or data memory.

The SAM8 instruction set supports seven explicit addressing modes. Not all of these addressing modes are available for each instruction:

— Register (R)
— Indirect Register (IR)
— Indexed (X)
— Direct Address (DA)
— Indirect Address (IA)
— Relative Address (RA)
— Immediate (IM)

REGISTER ADDRESSING MODE (R)

In Register addressing mode, the operand is the content of a specified register or register pair (see Figure 3-1). Working register addressing differs from Register addressing as it uses a register pointer to specify an 8-byte working register space in the register file and an 8-bit register within that space (see Figure 3-2).
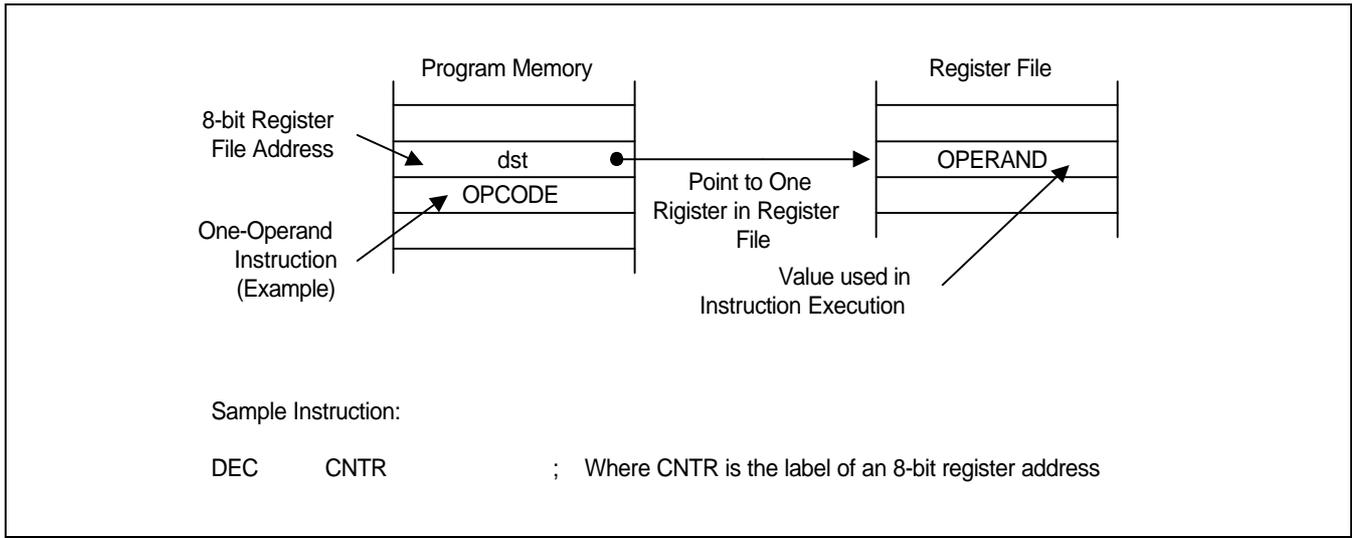

Figure 3-1. Register Addressing
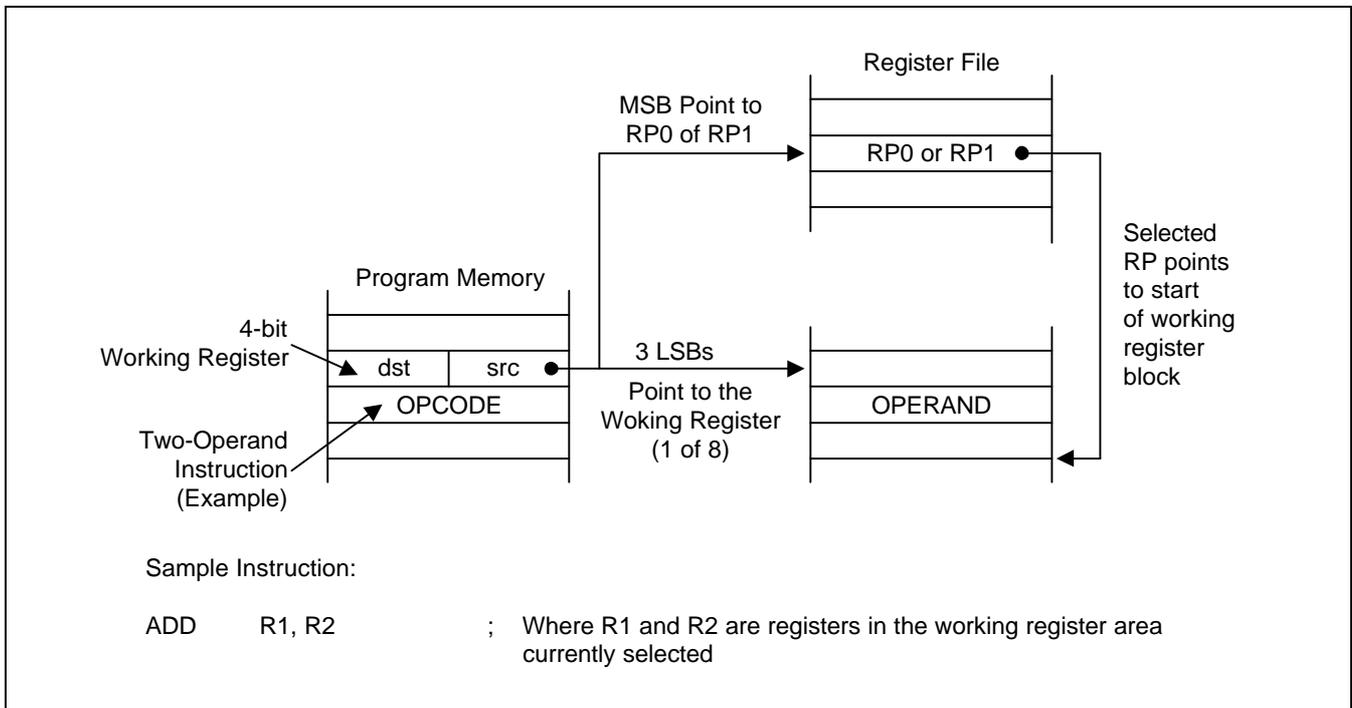

Figure 3-2. Working Register Addressing

INDIRECT REGISTER ADDRESSING MODE (IR)

In Indirect Register (IR) addressing mode, the content of the specified register or register pair is the address of the operand. Depending on the instruction used, the actual address may point to a register in the register file, to program memory (ROM), or to an external memory space, if implemented (see Figures 3-3 through 3-6).

You can use any 8-bit register to indirectly address another register. Any 16-bit register pair can be used to indirectly address another memory location. Remember, however, that locations C0H–FFH in set 1 cannot be accessed using Indirect Register addressing mode.

INDEXED ADDRESSING MODE (X)

Indexed (X) addressing mode adds an offset value to a base address during instruction execution in order to calculate the effective operand address (see Figure 3-7). You can use Indexed addressing mode to access locations in the internal register file or in external memory (if implemented). You cannot, however, access locations C0H–FFH in set 1 using Indexed addressing.

In short offset Indexed addressing mode, the 8-bit displacement is treated as a signed integer in the range from –128 to +127. This applies to external memory accesses only (see Figure 3-8).

For register file addressing, an 8-bit base address provided by the instruction is added to an 8-bit offset contained in a working register. For external memory access, the base address is stored in the working register pair designated in the instruction. The 8-bit or 16-bit offset given in the instruction is then added to the base address (see Figure 3-9).

The only instruction that supports Indexed addressing mode for the internal register file is the Load instruction (LD). The LDC and LDE instructions support Indexed addressing mode for internal program memory and for external data memory (if implemented).
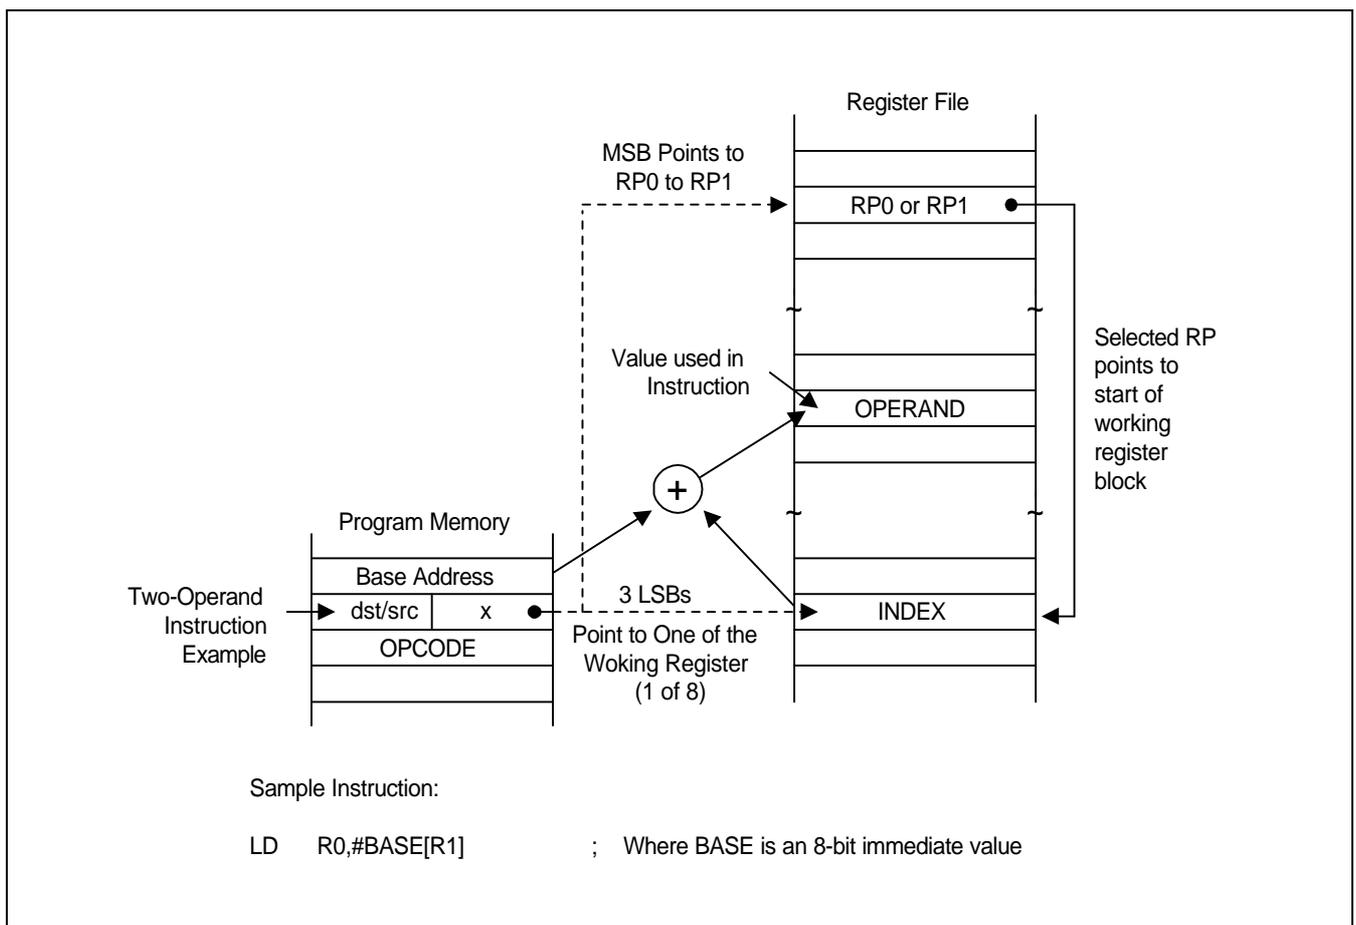

Figure 3-7. Indexed Addressing to Register File

INDEXED ADDRESSING MODE (Continued)
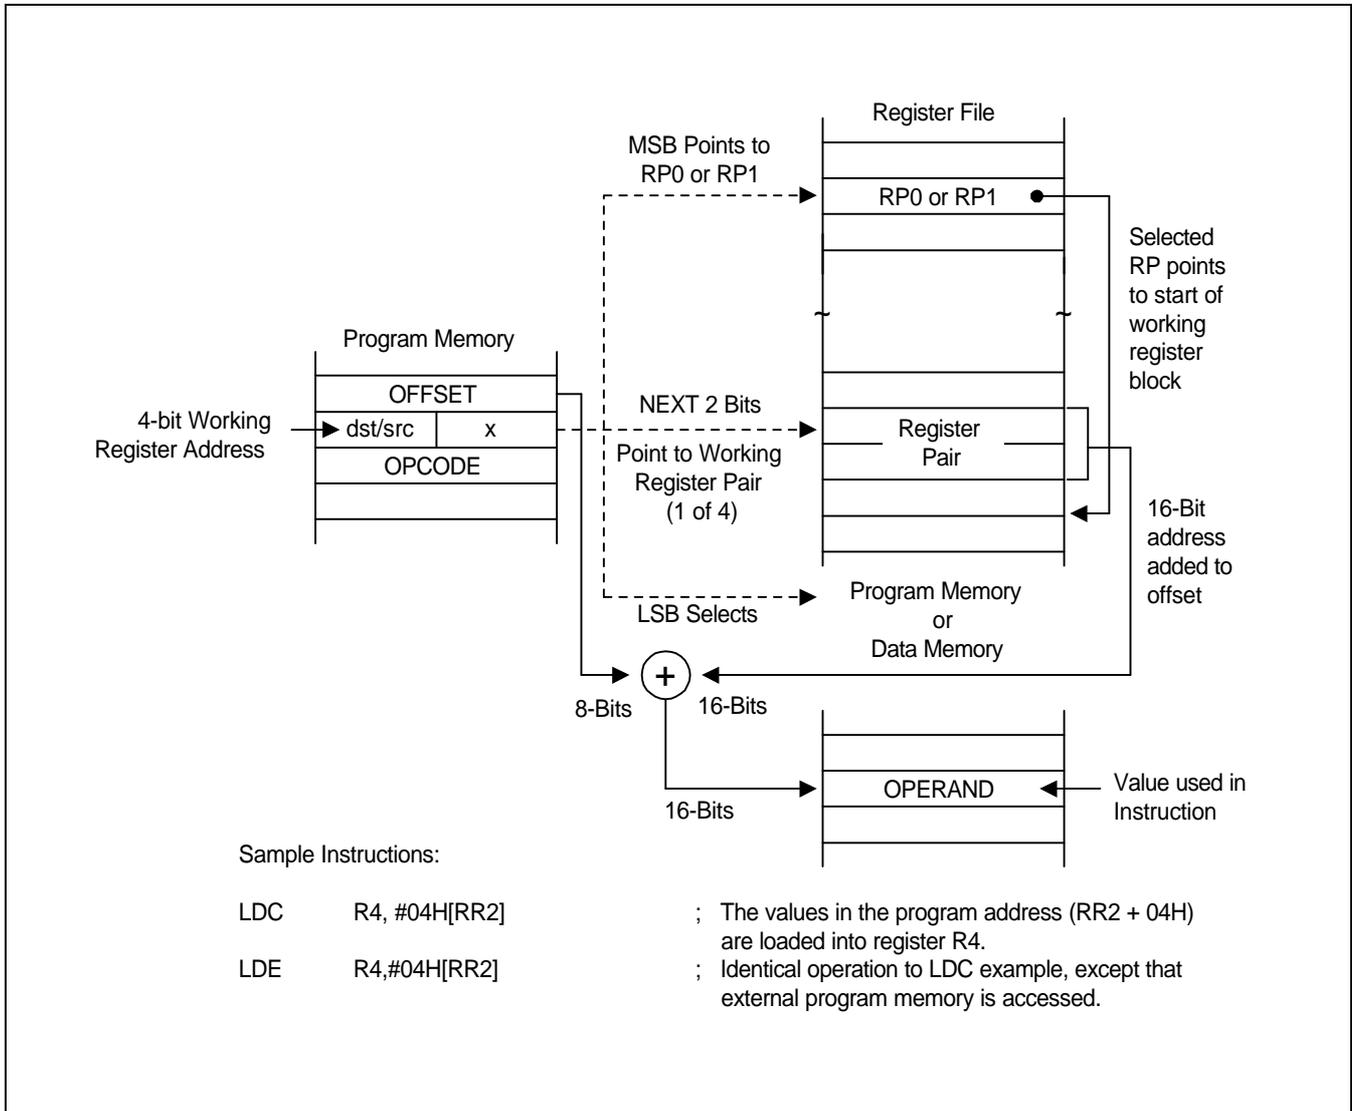

Figure 3-8. Indexed Addressing to Program or Data Memory with Short Offset

SAMSUNG
ELECTRONICS

INDEXED ADDRESSING MODE (Concluded)

Figure 3-9. Indexed Addressing to Program or Data Memory

DIRECT ADDRESS MODE (DA)

In Direct Address (DA) mode, the instruction provides the operand's 16-bit memory address. Jump (JP) and Call (CALL) instructions use this addressing mode to specify the 16-bit destination address that is loaded into the PC whenever a JP or CALL instruction is executed.

The LDC and LDE instructions can use Direct Address mode to specify the source or destination address for Load operations to program memory (LDC) or to external data memory (LDE), if implemented.

JP   C,JOB1   ;   Where JOB1 is a 16-bit immediate address
CALL   DISPLAY   ;   Where DISPLAY is a 16-bit immediate address
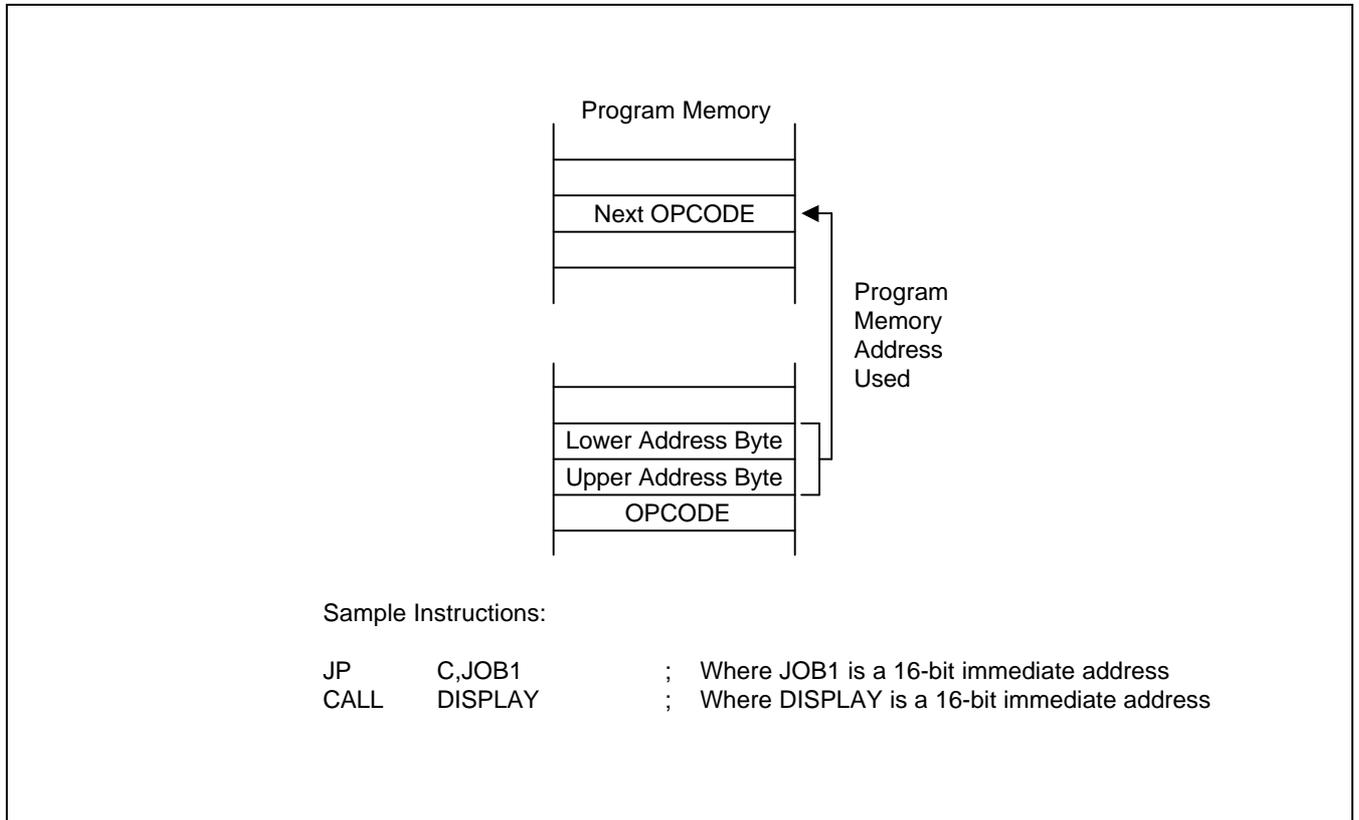

Figure 3-11. Direct Addressing for Call and Jump Instructions

INDIRECT ADDRESS MODE (IA)

In Indirect Address (IA) mode, the instruction specifies an address located in the lowest 256 bytes of the program memory. The selected pair of memory locations contains the actual address of the next instruction to be executed. Only the CALL instruction can use Indirect Address mode.

Because Indirect Address mode assumes that the operand is located in the lowest 256 bytes of program memory, only an 8-bit address is supplied in the instruction. The upper bytes of the destination address are assumed to be all zeros.
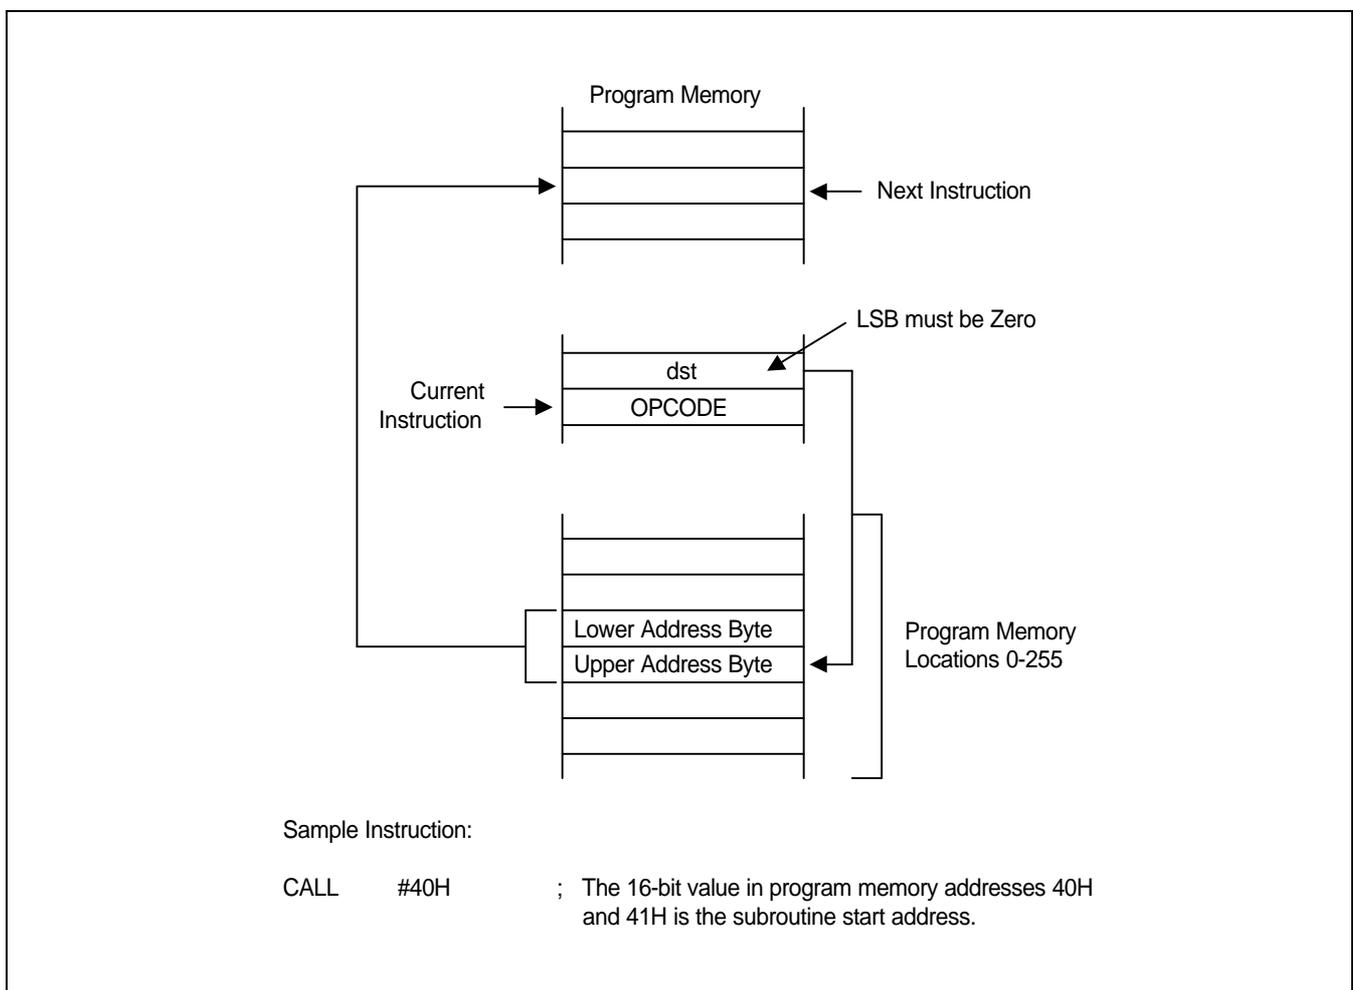

Figure 3-12. Indirect Addressing

RELATIVE ADDRESS MODE (RA)

In Relative Address (RA) mode, a two's-complement signed displacement between – 128 and + 127 is specified in the instruction. The displacement value is then added to the current PC value. The result is the address of the next instruction to be executed. Before this addition occurs, the PC contains the address of the next instruction immediately following the current instruction.

Several program control instructions use the Relative Address mode to perform conditional jumps. The instructions that support RA addressing are BTJRF, BTJRT, DJNZ, CPIJE, CPIJNE, and JR.
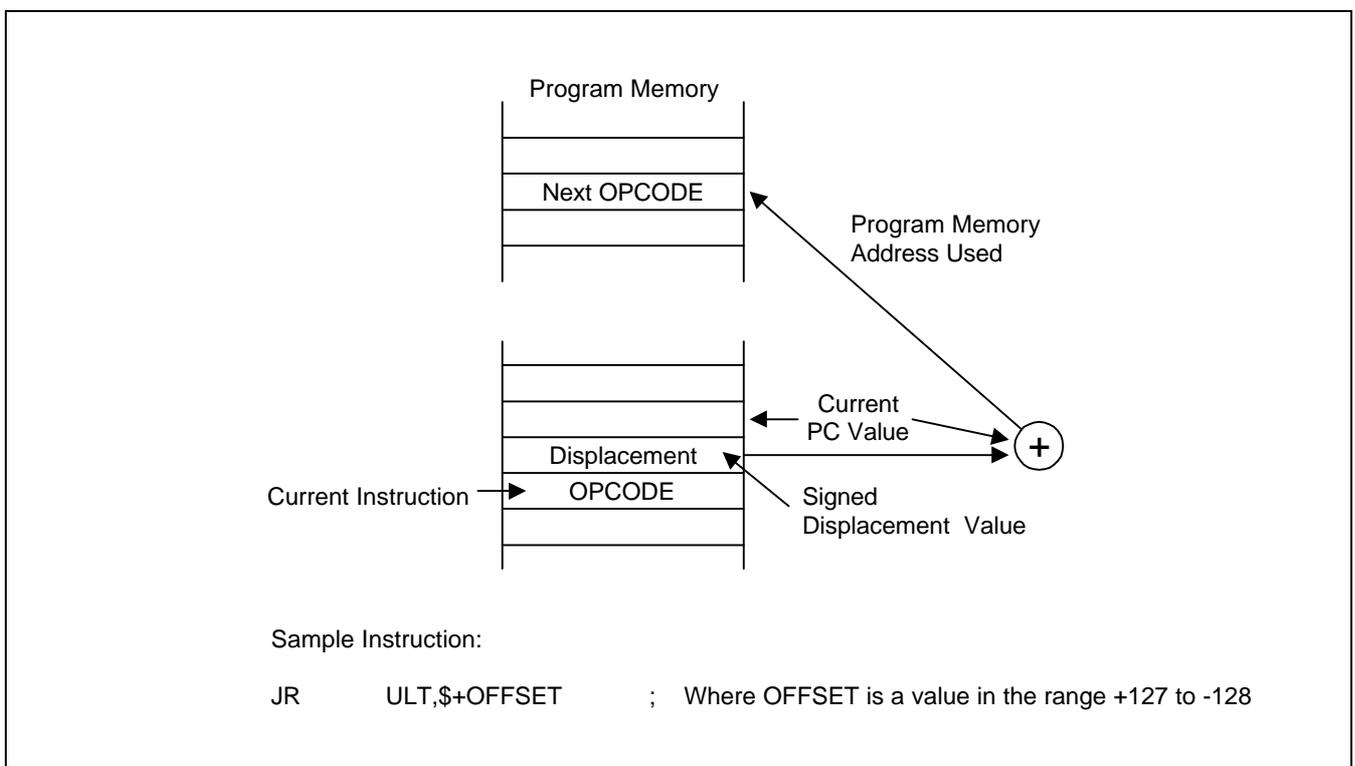

Figure 3-13. Relative Addressing

IMMEDIATE MODE (IM)

In Immediate (IM) mode, the operand value used in the instruction is the value supplied in the operand field itself. The operand may be one byte or one word in length, depending on the instruction used. Immediate addressing mode is useful for loading constant values into registers.

CONTROL REGISTERS

OVERVIEW

In this chapter, detailed descriptions of the S3C8639/C863A/C8647 control registers are presented in an easy-to-read format. You can use this chapter as a quick-reference source when writing application programs.

The locations and read/write characteristics of all mapped registers in the S3C8639/C863A/C8647 register files are presented in Tables 4-1, 4-2, and 4-3. The hardware reset values for these registers are described in Chapter 8, "RESET and Power-Down."

Figure 4-1 illustrates the important features of the standard register description format.

Control register descriptions are arranged in alphabetical order according to register mnemonic. More detailed information about control registers is presented in the context of the specific peripheral hardware descriptions in Part II of this manual.

Table 4-1. Set 1 Registers

Register Name	Mnemonic	Decimal	Hex	R/W

.6 and .5   **Main Oscillator Stop Control Bits**

0	0	No effect
0	1	No effect
1	0	Stop main oscillator
1	1	No effect

.4 and .3   **CPU Clock (System Clock) Selection Bits [1]**

0	0	Divide by 16 ($f_{OSC}/16$)
0	1	Divide by 8 ($f_{OSC}/8$)
1	0	Divide by 2 ($f_{OSC}/2$)
1	1	Non-divided clock (f_{OSC}) [2]

.2–.0   **Subsystem Clock Selection Bits [3]**

1	0	1	Invalid setting for S3C8639/C863A/C8647
Others			Select main system clock (MCLK)

NOTES:
1. After a reset, the slowest clock (divided by 16) is selected as the system clock. To select faster clock speeds, load the appropriate values to CLKCON.3 and CLKCON.4.
2. If the oscillator frequency is higher than 12 MHz, this selection is invalid.
3. These selection bits are required only for systems that have a main clock and a subsystem clock. S3C8639/C863A/C8647 use only the main oscillator clock circuit. For this reason, the setting "101B" is invalid.

SAMSUNG
ELECTRONICS

DAR0 — DDC Address Register 0   EAH   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	1	0	1	0	–	–	–	–
Read/Write	R/W	R/W	R/W	R/W	–	–	–	–
Addressing Mode	Register addressing mode only							

.7–.4	4-Slave Address Bits
	These bits are operate only when receive the slave address. Read enable anytime. Write enable when DCSR0.4 is "0".

.3–.0	Not used for the S3C8639/C863A/C8647

DAR1 — DDC Address Register 1   EEH   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	–
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	–
Addressing Mode	Register addressing mode only							

.7–.1	7-Slave Address Bits
	These bits are operate only when receive the slave address. Read enable anytime. Write enable when DCSR0.4 is "0".

.0	Not used for the S3C8639/C863A/C8647

DCCR — DDC Clock Control Register   EBH   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	1	1	1	1
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7

Transmit acknowledgement enable mode when this bit is "1".

.6

Tx Clock Selection Bit

0	f_{OSC}/10
1	f_{OSC}/256

.5

DDC Module Interrupt Enable Bit

0	Disable interrupt
1	Enable interrupt

.4

DDC Module Interrupt Pending Bit

0	When write "0" to this bit (write "1" has no effect)
0	When DCSR0.4 is "0"
1	When slave address match occurred
1	When arbitration lost (master mode)
1	When an 1-byte transmit or receive operation is terminated
1	As soon as the DDC1 mode is enabled after the prebuffer is used

.3–.0

Transmit Clock 4-Bit Prescaler Bits (CCR3–CCR0)

SCL clock = IICLK/(CCR < 3: 0 > +1) where, IICLK is f_{OSC}/10 when DCCR.6 is "0" IICLK is f_{OSC}/256 when DCCR.6 is "1"

DCON — DDC Control Register   E9H   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	–	–	–	1	0	0	0
Read/Write	–	–	–	–	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.4	Not used for the S3C8639/C863A/C8647.

.3 — **Tx/Rx Pre-Buffer Data Registers Enable Bit**

0	Normal IIC-bus mode (Pre-buffer data registers are not used.)
1	Pre-buffer data registers enable mode. This bit is set by writing "1" or by a reset.

.2 — **DDC Address Match Bit**

0	When start or stop or reset
1	When DDC received address matchs to DAR0 register

.1 — **DDC1 Tx Mode Enable Bit**

0	IIC-bus interface mode (SCL pin is also selected)
1	DDC1 Tx mode (VCLK pin is also selected)

.0 — **SCL Pin Falling Edge Detection Flag (note)**

0	SCL pin level remains high after a reset (when read)
0	*This bit can be cleared by S/W written "0" (when write)*
1	Falling edge can be detected at the SCL pin after a reset or after this flag is cleared by software (when read) After start condition, the clock source of DDC module automatically charges from VCLK (Vsync-I) to SCL0 (DCON.1 is "1" to "0") and slave address match possible.
1	*No effect (when write)*

NOTE: When DDC interrupt is occurred, the SCL line is not pull-down in the DDC1 mode and Tx/Rx pre-buffer data registers enable bit, DCON.3 is "1" (only slave mode).

DCSR0 — DDC Control/Status Register 0   ECH   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	–	0
Read/Write	R/W	R/W	R/W	R/W	R	R	–	R
Addressing Mode	Register addressing mode only							

.7–.6   **Master/Slave, Tx/Rx Mode Selection Bits**

0	0	Slave receiver mode (Default mode)
0	1	Slave transmitter mode
1	0	Master receiver mode
1	1	Master transmitter mode

.5   **Bus Busy Bit**

0	IIC-bus is not busy (when read), stop condition generation (when write)
1	IIC-bus is busy (when read), start condition generation (when write)

.4   **DDC Module Enable Bit**

0	Disable DDC module
1	Enable DDC module

.3   **Arbitration Lost Bit**

0	Bus arbitration status okay
1	Bus arbitration failed during serial I/O

.2   **DDC Address/Data classification Bit**

0	When reset or start/stop condition is generated, or when the received data is in the data field.
1	When the received slave address matchs to DAR0, DAR1 register

.1

Not used for the S3C8639/C863A/C8647

.0   **Received Acknowledgement (ACK) Bit**

0	ACK is received
1	ACK is not received

NOTE: Bits 3–0 are read only.

SAMSUNG
ELECTRONICS

DCSR1 — DDC Control/Status Register 1   EDH   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	–	–	–	–	0	1	0
Read/Write	–	–	–	–	–	R/W	R/W	R/W

Addressing Mode   Register addressing mode only

.7–.3	Not used for the S3C8639/C863A/C8647

.2   **Stop Condition Detection Bit**

0	When it writes "0" to this bit, it is reset or master mode.
1	When a STOP condition is detected after START and slave address reception

.1   **Data Buffer Empty Status Bit**

0	When the CPU writes the transmitted data into the TBDR register
1	When the data of the TBDR register is loads to the DDSR register or when a STOP condition is detected in DCSR0.7-.6 (slave transmitter mode) = "01"

.0   **Data Buffer Full Status Bit**

0	When the CPU reads the received data from the RBDR register or STOP condition
1	When the data or matched address is transferred from the DDSR register to the RBDR register

DDSR — DDC Data Shift Register   F1H   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0	Write enable when DCSR0.4 is "1" and DCON.3 is "0". Read enable anytime.

SAMSUNG
ELECTRONICS

EMT — External Memory Timing Register   FEH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	1	1	1	1	1	0	–
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	–
Addressing Mode	Register addressing mode only							

.7 **External WAIT Input Function Enable Bit**

0	Disable WAIT input function for external device
1	Enable WAIT input function for external device

.6 **Slow Memory Timing Enable Bit**

0	Disable slow memory timing
1	Enable slow memory timing

.5 and .4 **Program Memory Automatic Wait Control Bits**

0	0	No wait (Normal Operation)
0	1	Wait one cycle
1	0	Wait two cycles
1	1	Wait three cycles

.3 and .2 **Data Memory Automatic Wait Control Bits**

0	0	No wait (Normal Operation)
0	1	Wait one cycle
1	0	Wait two cycles
1	1	Wait three cycles

.1 **Stack Area Selection Bit**

0	Select internal register file area
1	Select external data memory area

.0

Not used for the S3C8639/C863A/C8647

NOTE: As external peripheral interface is not implemented in S3C8639/C863A/C8647, EMT register is not used. The program initialization routine should clear the EMT register to "00H" after a reset. Modification of EMT values during the normal operation may cause a system malfunction.

FLAGS — System Flags Register   D5H   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 **Carry Flag (C)**

0	Operation does not generate a carry or borrow condition
1	Operation generates a carry-out or borrow into high-order bit 7

.6 **Zero Flag (Z)**

0	Operation result is a non-zero value
1	Operation result is zero

.5 **Sign Flag (S)**

0	Operation generates a positive number (MSB = "0")
1	Operation generates a negative number (MSB = "1")

.4 **Overflow Flag (V)**

0	Operation result is $\leq$ +127 or $\geq$ −128
1	Operation result is > +127 or < −128

.3 **Decimal Adjust Flag (D)**

0	Add operation completed
1	Subtraction operation completed

.2 **Half-Carry Flag (H)**

0	No carry-out of bit 3 or no borrow into bit 3 by addition or subtraction
1	Addition generated carry-out of bit 3 or subtraction generated borrow into bit 3

.1 **Fast Interrupt Status Flag (FIS)**

0	Cleared automatically during an interrupt return (IRET)
1	Automatically set to logic one during a fast interrupt service routine

.0 **Bank Address Selection Flag (BA)**

0	Bank 0 is selected (by executing the instruction SB0)
1	Bank 1 is selected (by executing the instruction SB1)

SAMSUNG
ELECTRONICS

IMR — Interrupt Mask Register   DDH   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Addressing Mode   Register addressing mode only

.7   **Interrupt Level 7 (IRQ7) Enable Bit; Slave Only IIC-Bus Interrupt (Only S3C863X)**

0	Disable IRQ7 interrupt
1	Enable IRQ7 interrupt

.6   **Interrupt Level 6 (IRQ6) Enable Bit; P0.2 External Interrupt (INT2)**

0	Disable IRQ6 interrupt
1	Enable IRQ6 interrupt

.5   **Interrupt Level 5 (IRQ5) Enable Bit; P0.1 External Interrupt (INT1)**

0	Disable IRQ5 interrupt
1	Enable IRQ5 interrupt

.4   **Interrupt Level 4 (IRQ4) Enable Bit; P0.0 External Interrupt (INT0)**

0	Disable IRQ4 interrupt
1	Enable IRQ4 interrupt

.3   **Interrupt Level 3 (IRQ3) Enable Bit; DDC (Multi-Master IIC-Bus) Interrupt**

0	Disable IRQ3 interrupt
1	Enable IRQ3 interrupt

.2   **Interrupt Level 2 (IRQ2) Enable Bit; Timer M1 Capture/Overflow Interrupt**

0	Disable IRQ2 interrupt
1	Enable IRQ2 interrupt

.1   **Interrupt Level 1 (IRQ1) Enable Bit; Timer M2 Interval Interrupt**

0	Disable IRQ1 interrupt
1	Enable IRQ1 interrupt

.0   **Interrupt Level 0 (IRQ0) Enable Bit; Timer M0 Overflow/Capture Interrupt**

0	Disable IRQ0 interrupt
1	Enable IRQ0 interrupt

SAMSUNG
ELECTRONICS

IPH — **Instruction Pointer (High Byte)** **DAH** **Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET **Value**	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0 **Instruction Pointer Address (High Byte)**

The high-byte instruction pointer value is the upper eight bits of the 16-bit instruction pointer address (IP15–IP8). The lower byte of the IP address is located in the IPL register (DBH).

IPL — **Instruction Pointer (Low Byte)** **DBH** **Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET **Value**	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0 **Instruction Pointer Address (Low Byte)**

The low-byte instruction pointer value is the lower eight bits of the 16-bit instruction pointer address (IP7–IP0). The upper byte of the IP address is located in the IPH register (DAH).

IPR — Interrupt Priority Register   FFH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7, .4 and .1   **Priority Control Bits for Interrupt Groups A, B and C**

0	0	0	Not used
0	0	1	B > C > A
0	1	0	A > B > C
0	1	1	B > A > C
1	0	0	C > A > B
1	0	1	C > B > A
1	1	0	A > C > B
1	1	1	Not used

.6   **Interrupt Sub-group C Priority Control Bit**

0	IRQ6 > IRQ7
1	IRQ7 > IRQ6

.5   **Interrupt Group C Priority Control Bit**

0	IRQ5 > (IRQ6, IRQ7)
1	(IRQ6, IRQ7) > IRQ5

.3   **Interrupt Sub-group B Priority Control Bit**

0	IRQ3 > IRQ4
1	IRQ4 > IRQ3

.2   **Interrupt Group B Priority Control Bit**

0	IRQ2 > (IRQ3, IRQ4)
1	(IRQ3, IRQ4) > IRQ2

.0   **Interrupt Group A Priority Control Bit**

0	IRQ0 > IRQ1
1	IRQ1 > IRQ0

NOTE: Interrupt group A is IRQ0 and IRQ1. Interrupt group B is IRQ2, IRQ3, and IRQ4. Interrupt group C is IRQ5, IRQ6 and IRQ7.

IRQ — Interrupt Request Register   DCH   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R	R	R	R	R	R	R	R
Addressing Mode	Register addressing mode only							

.7   **Level 7 (IRQ7) Request Pending Bit; Slave Only IIC-Bus Interrupt (Only S3C863X)**

0	No IRQ7 interrupt pending
1	IRQ7 interrupt is pending

.6   **Level 6 (IRQ6) Request Pending Bit; P0.2 External Interrupt (INT2)**

0	No IRQ6 interrupt pending
1	IRQ6 interrupt is pending

.5   **Level 5 (IRQ5) Request Pending Bit; P0.1 External Interrupt (INT1)**

0	No IRQ5 interrupt pending
1	IRQ5 interrupt is pending

.4   **Level 4 (IRQ4) Request Pending Bit; P0.0 External Interrupt (INT0)**

0	No IRQ4 interrupt pending
1	IRQ4 interrupt is pending

.3   **Level 3 (IRQ3) Request Pending Bit; DDC (Multi-Master IIC-Bus) Interrupt**

0	No IRQ3 interrupt pending
1	IRQ3 interrupt is pending

.2   **Level 2 (IRQ2) Request Pending Bit; Timer M1 Capture/Overflow Interrupt**

0	No IRQ2 interrupt pending
1	IRQ2 interrupt is pending

.1   **Level 1 (IRQ1) Request Pending Bit; Timer M2 Interval Interrupt**

0	No IRQ1 interrupt pending
1	IRQ1 interrupt is pending

.0   **Level 0 (IRQ0) Request Pending Bit; Timer M0 Overflow/Capture Interrupt**

0	No IRQ0 interrupt pending
1	IRQ0 interrupt is pending

ELECTRONICS

P0INT — Port 0 External Interrupt Control Register   EBH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	0	0	0	–	0	0	0
Read/Write	–	R/W	R/W	R/W	–	R/W	R/W	R/W

Addressing Mode   Register addressing mode only

.7 and .3	Not used for the S3C8639/C863A/C8647

.6   **P0.2 External Interrupt (INT2, IRQ6) Pending Flag** (note)

0	No P0.2 external interrupt pending (when read)
0	*Clear P0.2 interrupt pending condition (when write)*
1	P0.2 external interrupt is pending (when read)

.5   **P0.1 External Interrupt (INT1, IRQ5) Pending Flag**

0	No P0.1 external interrupt pending (when read)
0	*Clear P0.1 interrupt pending condition (when write)*
1	P0.1 external interrupt is pending (when read)

.4   **P0.0 External Interrupt (INT0, IRQ4) Pending Flag**

0	No P0.0 external interrupt pending (when read)
0	*Clear P0.0 interrupt pending condition (when write)*
1	P0.0 external interrupt is pending (when read)

.2   **P0.2 External Interrupt (INT2, IRQ6) Enable Bit**

0	Disable P0.2 interrupt
1	Enable P0.2 interrupt

.1   **P0.1 External Interrupt (INT1, IRQ5) Enable Bit**

0	Disable P0.1 interrupt
1	Enable P0.1 interrupt

.0   **P0.0 External Interrupt (INT0, IRQ4) Enable Bit**

0	Disable P0.0 interrupt
1	Enable P0.0 interrupt

NOTE: Writing a "1" to an interrupt pending flag (P0.2, P0.1, P0.0) has no effect.

P1CON — Port 1 Control Register (Only S3C863X)   E6H   Set 1, Bank 0

.3 and .2   **P3.5 Mode Selection Bits**

0	0	Input mode
0	1	Input mode with pull-up resistor
1	0	Push-pull output mode
1	1	N-channel open-drain output mode

.1 and .0   **P3.4 Mode Selection Bits**

0	0	Input mode
0	1	Input mode with pull-up resistor
1	0	Push-pull output mode
1	1	N-channel open-drain output mode

P3CONL — Port 3 Control Register (Low Byte)   EAH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only						

.7 and .6   **P3.3/AD3 Mode Selection Bits**

0	0	Input mode
0	1	Analog Input mode (AD3)
1	0	Push-pull output mode
1	1	N-channel open-drain output mode

.5 and .4   **P3.2/AD2 Mode Selection Bits**

0	0	Input mode
0	1	Analog Input mode (AD2)
1	0	Push-pull output mode
1	1	N-channel open-drain output mode

.3 and .2   **P3.1/AD1 Mode Selection Bits**

0	0	Input mode
0	1	Analog Input mode (AD1)
1	0	Push-pull output mode
1	1	N-channel open-drain output mode

.1 and .0   **P3.0/AD0 Mode Selection Bits**

0	0	Input mode
0	1	Analog Input mode (AD0)
1	0	Push-pull output mode
1	1	N-channel open-drain output mode

SAMSUNG
ELECTRONICS

PHGEN – Pseudo Hsync Generation Register   F9H   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	1	0	1	0	0	1	1
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Addressing Mode   Register addressing mode only

.7–.0	Write enable when SYNCON2.4 is "0". (General Pseudo H/Vsync generation mode) Read enable any time

PP — Page Pointer Register   DFH   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.4   **Destination Register Page Selection Bits**

0	0	0	0	Destination: page 0
0	0	0	1	Destination: page 1
0	0	1	0	Destination: page 2 (Not used for the S3C8647)
0	0	1	1	Destination: page 3 (Not used for the S3C8639)
0	1	0	0	Not used for the S3C8639/C863A/C8647
•	•	•		•
1	1	1	1	Not used for the S3C8639/C863A/C8647

.3–.0   **Source Register Page Selection Bits**

0	0	0	0	Source: page 0
0	0	0	1	Source: page 1
0	0	1	0	Source: page 2 (Not used for the S3C8647)
0	0	1	1	Source: page 3 (Not used for the S3C8639)
0	1	0	0	Not used for the S3C8639/C863A/C8647

1	1	1	1	Not used for the S3C8639/C863A/C8647

SAMSUNG
ELECTRONICS

PVGEN – Pseudo Vsync Generation Register   FAH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET **Value**	0	1	0	1	0	0	1	1
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Addressing Mode   Register addressing mode only

.7–.0	Write enable SYNCON2.4 is "0". (General Pseudo H/Vsync generation mode) Read enable any time

PWMCON — PWM Control Register   E7H   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	–	–	–	–	–
Read/Write	R/W	R/W	R/W	–	–	–	–	–
Addressing Mode	Register addressing mode only							

.7 and .6   **2-Bit Prescaler Value for PWM Counter Input Clock**

0	0	Non-divided input clock
0	1	Input clock divided into two
1	0	Input clock divided into three
1	1	Input clock divided into four

.5   **PWM Counter Enable Bit**

0	Stop PWM counter operation (No current leakage)
1	Start (or resume) PWM counter operation

.4–.0 | Not used for the S3C8639/C863A/C8647 |

SAMSUNG
ELECTRONICS

RBDR — Receive Pre-Buffer Data Register   F0H   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R	R	R	R	R	R	R	R

Addressing Mode   Register addressing mode only

.7–.0

> It is a read-only register. Read enable anytime. This register will be updated after a data byte is received when the DCSR0.2 is "1" and the DCSR1.0 will be "1". The read operation of this register will clear the DCSR1.0. After the DCSR1.0 is cleared, the register can load the received data again and set the DCSR1.0.

RP0 — Register Pointer 0   D6H   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	1	1	0	0	0	–	–	–
Read/Write	R/W	R/W	R/W	R/W	R/W	–	–	–
Addressing Mode	Register addressing only							

.7–.3   **Register Pointer 0 Address Value**

Register pointer 0 can independently point to one of the 18 8-byte working register areas in the register file. Using the register pointers, RP0 and RP1, you can select two 8-byte register slices at one time as active working register space. After a reset, RP0 points to address C0H in register set 1, selecting the 8-byte working register slice C0H–C7H.

.2–.0   Not used for the S3C8639/C863A/C8647

RP1 — Register Pointer 1   D7H   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	1	1	0	0	1	–	–	–
Read/Write	R/W	R/W	R/W	R/W	R/W	–	–	–
Addressing Mode	Register addressing only							

.7–.3   **Register Pointer 1 Address Value**

Register pointer 1 can independently point to one of the 18 8-byte working register areas in the register file. Using the register pointers, RP0 and RP1, you can select two 8-byte register slices at one time as active working register space. After a reset, RP1 points to address C8H in register set 1, selecting the 8-byte working register slice C8H–CFH.

.2–.0   Not used for the S3C8639/C863A/C8647

SAMSUNG
ELECTRONICS

SIAR — Slave IIC-Bus Address Register (Only S3C863X)   F3H   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	–
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	–
Addressing Mode	Register addressing only							

.7–.1	**7-Bit Slave Address Bits**
	These bits are operated only when receive the slave address and general call. Write enable when SICSR.6 is "0", but read enable anytime.

.0	Not used for the S3C8639/C863A/C8647

SICSR — Slave IIC-Bus Control/Status Register (Only S3C863X)   F2H

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R	R	R

Addressing Mode   Register addressing mode only

.7   **Acknowledgement Enable Bit**

0	Disable ACK generation
1	Enable ACK generation

.6   **Slave IIC-Bus Module Enable Bit**

0	Disable IIC-Bus module
1	Enable IIC-Bus module (Enable serial data Tx/Rx)

.5   **Slave IIC-Bus Tx/Rx Interrupt Enable Bit**

0	Disable interrupt
1	Enable interrupt

.4   **Slave IIC-Bus Tx/Rx Interrupt Pending Bit**

0	No interrupt pending (when read) clear pending condition (when write)
0	When SICSR.6 is "0"
1	When 1-Byte Tx/Rx is terminated
1	When slave address match occurred

.3   **Slave IIC-Bus Tx/Rx Mode Status Bit**

0	Slave receive mode (Default mode)
1	Slave transmitter mode

.2   **IIC-Bus Busy Status Bit**

0	IIC-Bus is not busy
1	IIC-Bus is busy

.1   **Slave Address Match Bit**

0	When start or stop or reset
1	When received slave address matchs to SIAR register

.0   **Received Acknowledge (ACK) Bit**

0	ACK is received
1	ACK is not received

NOTE: Bit 2-0 are read only.

SAMSUNG
ELECTRONICS

SIDSR — Slave IIC-Bus Tx/Rx Data Shift Register (Only S3C863X)   F4H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Addressing Mode   Register addressing only

.7–.0   **Slave IIC-Bus Transmit/Receive Data Shift Bus**

Write enable when SICSR.6 is "1", but read enable anytime.

SPH — Stack Pointer (High Byte)   D8H   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0   **Stack Pointer Address (High Byte)**

The high-byte stack pointer value is the upper eight bits of the 16-bit stack pointer address (SP15–SP8). The lower byte of the stack pointer value is located in the register SPL (D9H). The SP value is undefined after a reset.

SPL — Stack Pointer (Low Byte)   D9H   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0   **Stack Pointer Address (Low Byte)**

The low-byte stack pointer value is the lower eight bits of the 16-bit stack pointer address (SP7–SP0). The upper byte of the stack pointer value is located in the register SPH (D8H). The SP value is undefined after a reset.

SAMSUNG
ELECTRONICS

STOPCON — Stop Control Register   FBH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0	**Stop Operation Enable Bits**

1 0 1 0 0 1 0 1	Enable the stop (power saving) function
Others	Disable the stop function

NOTES:

1. If you intend to stop function for power saving, before Stop OP-code, you must set this register value to A5H (10100101B).
2. When STOP mode is released, stop control register (STOPCON) value is cleared automatically.

SYM — System Mode Register   DEH   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	–	–	x	x	x	0	0
Read/Write	R/W	–	–	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7   **Tri-State External Interface Control Bit [1]**

0	Normal operation (disable tri-state operation)
1	Set external interface lines to high impedance (enable tri-state operation)

.6 and .5

Not used for the S3C8639/C863A/C8647

.4–.2   **Fast Interrupt Level Selection Bits [2]**

0	0	0	IRQ0
0	0	1	IRQ1
0	1	0	IRQ2
0	1	1	IRQ3
1	0	0	IRQ4
1	0	1	IRQ5
1	1	0	IRQ6
1	1	1	IRQ7 (Not used for the S3C8647)

.1   **Fast Interrupt Enable Bit [3]**

0	Disable fast interrupt processing
1	Enable fast interrupt processing

.0   **Global Interrupt Enable Bit [4]**

0	Disable global interrupt processing
1	Enable global interrupt processing

NOTES:
1. As external interface is not implemented in S3C8639/C863A/C8647, SYM.7 must always be "0".
2. You can select only one interrupt level at a time for fast interrupt processing.
3. Setting SYM.1 to "1" enables fast interrupt processing for the interrupt level currently selected by SYM.2–SYM.4.
4. After a reset, you must enable global interrupt processing by executing an EI instruction (not by writing a "1" to SYM.0).

SAMSUNG
ELECTRONICS

SYNCON0 — Sync Processor Control Register 0

EDH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R	R	R	R	R

Addressing Mode   Register addressing mode only

.7   Sync Input Selection (SIS) Bit

0	Hsync-I input is selected
1	Csync-I input is selected

.6   Hsync Blanking Enable Bit

0	Disable (Hsync signal by-pass) (When SYNCON0.5 = "0")
1	Enable Hsync blanking automatically (During the Vsync signal extraction period) (When SYNCON0.5 = "1")

.5   Vsync-O Output Selection (VOS) Bit

0	Select Vsync-I port input (when separate sync input mode)
1	Select 5-bit compare output (when composite sync input mode)

.4–.0   5-Bit Counter Value Bits

5-bit counter increases when a high level is detected, while an overflow dose not occur (Stop at "11111"). It decreases when a low level is detected, while an underflow does not occur (Stop at "00000") When SYNCON0.5 is "1": Sync separation and output (When counter value increases to "11111", output the high through the MUX and when counter value decreases to "00000", output becomes low. Resume the previous status when "11111" > counter value > "00000")

SYNCON1 — Sync Processor Control Register 1   EEH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET **Value**	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Addressing Mode   Register addressing mode only

.7 and .6   **Clamp Signal Generator Selection Bits**

0	0	Inhibit Clamp signal output (Clamp-O)
0	1	($f_{OSC} \times 2$) clock pulse output (250 ns at 8 MHz f_{OSC})
1	0	($f_{OSC} \times 4$) clock pulse output (500 ns at 8 MHz f_{OSC}, 333 ns at 12 MHz f_{OSC})
1	1	($f_{OSC} \times 8$) clock pulse output (1 µs at 8 MHz f_{OSC}, 666ns at 12 MHz f_{OSC})

.5   **"Front Porch"/"Back Porch" Mode Selection Bit**

0	Generate Clamp-O after the rising edge of Hsync ("front porch" mode)
1	Generate Clamp-O after the falling edge of Hsync ("back porch" mode)

.4   **Clamp Signal Output Status Control Bit (COSC)**

0	Negative polarity
1	Positive polarity

.3   **Vsync-O Status Control Bit**

0	Do not invert (by-pass)
1	Invert output signal

.2   **Hsync-O Status Control Bit (HOSC)**

0	Do not invert (by-pass)
1	Invert output signal

.1   **Vsync Polarity Detection Bit [1]**

0	Negative polarity
1	Positive polarity

.0   **Hsync Polarity Detection Bit [2]**

0	Negative polarity
1	Positive polarity

NOTES:
1. To check Hsync/Vsync polarity, it uses 16 clocks of timer M2 ($f_{OSC}/1000$). If the Vsync polarity is changing, this bit will be updated after a typical delay of 2 ms, at 8 MHz f_{OSC} (1.33 ms at 12 MHz f_{OSC}).
2. The SYNCON1.0 may not be accurate when the Hsync-I is composite-sync signal output.   .

SAMSUNG
ELECTRONICS

SYNCON2 — Sync Processor Control Register 2 EFH Set 1, Bank 0

Bit Identifier	.7	–	.5	.4	.3	.2	.1	.0
RESET Value	0	–	0	0	0	0	0	0
Read/Write	R/W	–	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7		Unmixed Hsync Detection Bit (When SYNCON0.5 is "1")
	0	Mixed Hsync period with Vsync of a composite sync input (This bit still cleared before being read this bit or it is been in mixed Hsync period)
	1	Unmixed Hsync periods

.6	Not used for the S3C8639/C863A/C8647(Only "0")

.5		5-Bit Counter Source Clock (fsync) Input Selection Bit [1]
	0	$f_{OSC}/3$ (when f_{CPU} is 12 MHz)
	1	$f_{OSC}/2$ (when f_{CPU} is 8 MHz)

.4		Pseudo Sync Generation Disable Bit (Positive Polarity Only)
	0	Enable Pseudo Hsync/Vsync generation
	1	Normal Sync-processor operation (by-pass)

.3		Sync Signal Output Disable Bit
	0	Enable Sync signal output
	1	Inhibit Sync signal output (Output level is low)

.2		SOG (Sync On Green) Detection Bit
	0	No SOG signal (when read)
	0	Clear SOG detection 6-bit counter (when write)
	1	Csync-I is SOG signal [2]

.1		5-Bit up/down Counter Latch Status Changing Detection Bit
	0	When the latch status is not changed or it writes"0" to this bit
	1	When the latch status changing is detected.

.0		V_{DD} Level Selection Bit for TTL Sync-Input Port (Not used for the S3C8647)
	0	When V_{DD} is +5 V
	1	When V_{DD} is +3 V

NOTES:
1. Countable maximum Hsync pulse width = 7.85 us (when fsync is 4 MHz)
2. To check SOG presence, it uses 64 Csync-I input edge signal.
3. The SYNCON2.1 can be used to check the presence of composite-sync signal input.

SYNCRD — Sync Processor Port Read Data Register   F0H   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	–	–	–	0	0	0	0
Read/Write	–	–	–	–	R	R	R	R
Addressing Mode	Register addressing mode only							

.7–.4

Not used for the S3C8639/C863A/C8647

.3   **Vertical Sync Signal Output Data Bit (Vsync-O)**

0	Low data
1	High data

.2   **Horizontal Sync Signal Output Data Bit (Hsync-O)**

0	Low data
1	High data

.1   **Vertical Sync Signal Input Data Bit (Vsync-I)**

0	Low data
1	High data

.0   **Horizontal Sync Signal Input Data Bit (Hsync-I)**

0	Low data
1	High data

TBDR — Transmit Pre-Buffer Data Register   EFH   Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0	Write enable when DCSR0.4 is "1", Read enable anytime When DCON.3 (TBDR Enable bit) = "1" and DCSR1.1 = "0", the data written into his register will be automatically downloaded to the DDC Data Shift Register (DDSR) and generate the interrupt request when the module detects the calling address is matched and the bit 0 of the received data is "1" (DCSR0.7-6 = "01") and when the data in the DDSR register has been transmitted with received acknowledge bit, DCSR0.0 = "0". At this interrupt service routine, the CPU must write the next data to the TBDR register to clear DCSR1.1 and for the auto downloading of data to the DDSR register after the data in the DDSR register is transmitted over again with DCSR0.0 = "0".When DCON.3 = "1" and DDSR1.1 = "1", the data stored in this register will not be downloaded to the DDSR register and generated the interrupt request when the module detects the calling address is matched and the bit 0 of the received data is "1". At this interrupt service routine, the CPU must write the current data and rewrite the next data to the TBDR register to clear DCSR1.1.
	If the master receiver doesn't acknowledge the transmitted data, DCSR0.0 = "1", the module will release the SDA line for master to generate STOP or Repeated START conditions.
	If DCON.3 (TBDR Enable bit) is "0", the module will pull-down the SCL line in the IIC-Bus interrupt service routine when the DCSR0.2 is "1". And the module will release the SCL line if the CPU writes a data to the DDSR registers and the interrupt pending bit is cleared.

TM0CON — Timer m0 Control Register   D2H   Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7   **Timer M0 Input Clock Selection Bit**

0	f_{OSC}/128
1	f_{OSC}/8

.6 and .5   **2 Bit Prescaler Bits**

0	0	No division
0	1	Divided by 2
1	0	Divided by 3
1	1	Divided by 4

.4   **Timer M0 Capture Mode Selection Bit**

0	Capture on rising mode
1	Capture on falling mode

.3   **Timer M0 Counter Clear Bit (TM0CLR)**

0	No effect
1	Clear timer M0 counter, TM0CNT (when write)

.2   **Timer M0 Overflow Interrupt Enable Bit (TM0OVINT) [1]**

0	Disable timer M0 overflow interrupt
1	Enable timer M0 overflow interrupt

.1   **Timer M0 Capture Interrupt Enable Bit (TM0INT)**

0	Disable timer M0 interrupt [2]
1	Enable timer M0 interrupt

.0   **Timer M0 Capture Input Selection Bit (TM0CAPSEL)**

0	TM0CAP input pin selection
1	Vsync output path selection from sync-processor

NOTES:
1. When the captured value is #0FFH, the overflow interrupt does not occurred. If the captured value is changed from #0FFH to #00H, the overflow interrupt occurs. When the captured value is #00H, the overflow interrupt occurs first.
2. When the timer M0 interrupt is disabled, the timer M0 overflow interrupt by f_{OSC} can happen.

SAMSUNG
ELECTRONICS

TM1CON — Timer M1 Control Register   F5H   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 **Capture Signal Source Selection Bit**

0	Signal from timer M2 interval time
1	Vsync-O from sync-processor

.6 **Vsync-O Capture Egde Selection Bit (When TM1CON.7 = "1")**

0	Capture Vsync-O (from sync-processor) on rising edge
1	Capture Vsync-O (from sync-processor) on falling edge

.5 **Timer M1 Capture Interrupt Enable Bit (TM1INT)**

0	Disable timer M1 capture
1	Enable timer M1 capture

.4 **Timer M1 Capture Pending Bit (TM1PND)**

0	Interrupt is not pending (when read)
0	Clear this pending bit (when write)
1	Interrupt is pending (when read)
1	No effect (when write)

.3 **Timer M1 Counter Clear Bit (TM1CLR; when write)**

0	No effect
1	Clear timer M1 counter

.2 **Timer M1 Overflow Interrupt Enable Bit (TM1OVF)**

0	Disable timer M1 overflow interrupt
1	Enable timer M1 overflow interrupt

.1–.0 **Timer M1 Clock Input Selection Bit**

0	0	Hsync-I or Csync-I from sync processor
0	1	$f_{OSC}/2$
1	0	$f_{OSC}/128$
1	1	$f_{OSC}/512$

TM2CON — **Timer M2 Control Register**   **F6H**   **Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET **Value**	1	1	1	1	1	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only

.7–.3   **5-bit Prescale Bits (TM2PS4–TM2PS0)**

0	0	0	0	0	No division
0	0	0	0	1	Divide by 2
0	0	0	1	0	Divide by 3
	•			•	
1	1	1	1	1	Divide by 32

.2   **Timer M2 Interrupt Enable Bit (TM2INT)**

0	Disable timer M2 interrupt
1	Enable timer M2 interrupt

.1 and .0   **Timer M2 Capture Interval Time Selection Bits (When TM2CON.5 is "1")**

0	0	Timer M2 interval (by pass)
0	1	Timer M2 interval $\times$ 10
1	0	Timer M2 interval $\times$ 20
1	1	Timer M2 interval $\times$ 30

NOTES:
1. When the timer M1 capture mode is enabled (TM1CON.5 = "1"), the value of 5/2-bit prescaler is changed only in the timer M1 capture interrupt routine.
2. When the timer M1 capture mode is disabled (TM1CON.5 = "0"), the value of 5-bit prescaler is changed only in the timer M2 interval interrupt routine.

SAMSUNG
ELECTRONICS

WDTCON — Watchdog Time Control Register   ECH   Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0

5 INTERRUPT STRUCTURE

OVERVIEW

The SAM8 interrupt structure has three basic components: levels, vectors, and sources. The CPU recognizes eight interrupt levels and supports up to 128 interrupt vectors. When a specific interrupt level has more than one vector address, the vector priorities are established in hardware. Each vector can have one or more sources.

Levels

Interrupt levels are the main unit for interrupt priority assignment and recognition. All peripherals and I/O blocks can issue interrupt requests. In other words, peripheral and I/O operations are interrupt-driven. There are eight interrupt levels: IRQ0–IRQ7, also called level 0–level 7. Each interrupt level directly corresponds to an interrupt request number (IRQn). The total number of interrupt levels used in the interrupt structure varies from device to device.

The interrupt level numbers 0 through 7 do not necessarily indicate the relative priority of the levels. They are just identifiers for the interrupt levels that are recognized by the CPU. The relative priority of different interrupt levels is determined by settings in the interrupt priority register, IPR. Interrupt group and subgroup logic controlled by IPR settings lets you define more complex priority relationships between different levels.

Vectors

Each interrupt level can have one or more interrupt vectors, or it may have no vector address assigned at all. The maximum number of vectors that can be supported for a given level is 128. (The actual number of vectors used for S3C8-series devices will always be much smaller.) If an interrupt level has more than one vector address, the vector priorities are set in hardware. S3C8639/C863A/C8647* have ten (nine)* vectors — one corresponding to each of the ten (nine)* possible interrupt sources.

Sources

A source is any peripheral that generates an interrupt. A source can be an external pin or a counter overflow. Each vector can have several interrupt sources. In the S3C8639/C863A/C8647* interrupt structure, each source has its own vector address.

When a service routine starts, the respective pending bit should be either cleared automatically by hardware or cleared "manually" by program software. The characteristics of the source's pending mechanism determine which method would be used to clear its respective pending bit.

INTERRUPT TYPES

The three components of the SAM8 interrupt structure described before — levels, vectors, and sources — are combined to determine the interrupt structure of an individual device and to make full use of its available interrupt logic. There are three possible combinations of interrupt structure components, called interrupt types 1, 2, and 3. The types differ in the number of vectors and interrupt sources assigned to each level (see Figure 5-1):

Type 1: One level (IRQn) + one vector (V_1) + one source (S_1)

Type 2: One level (IRQn) + one vector (V_1) + multiple sources (S_1– S_n)

Type 3: One level (IRQn) + multiple vectors (V_1– V_n) + multiple sources (S_1– S_n , S_{n+1}– S_{n+m})

In the S3C8639/C863A/C8647 microcontrollers, only interrupt types 1 and 3 are implemented.
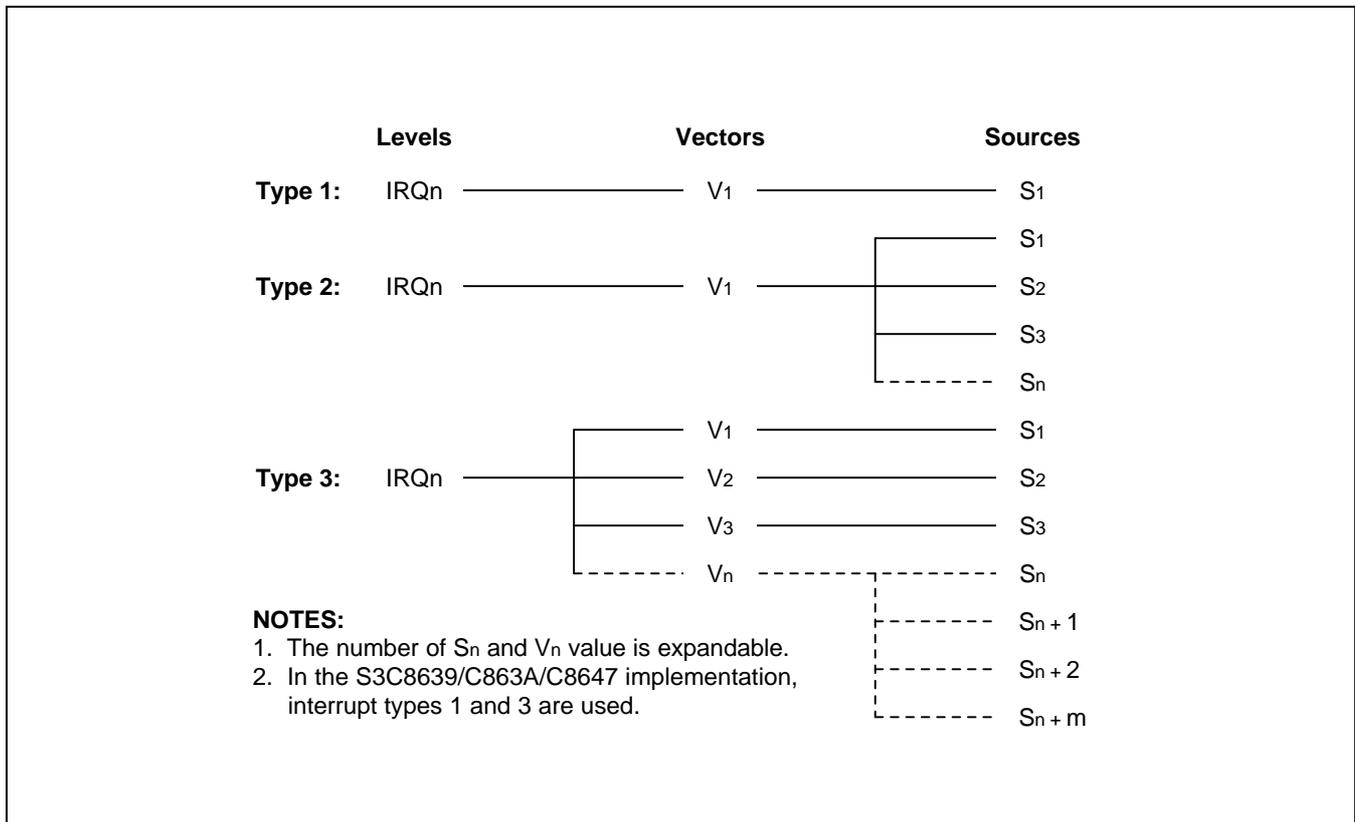

Figure 5-1. S3C8-Series Interrupt Types

SAMSUNG
ELECTRONICS

S3C8639/C863A/C8647 INTERRUPT STRUCTURE

The S3C8639/C863A/C8647 microcontrollers support ten interrupt sources. Each interrupt source has a corresponding interrupt vector address. All eight interrupt levels are used in the device-specific interrupt structure, which is shown in Figure 5-2.

When multiple interrupt levels are active, the interrupt priority register (IPR) determines the order in which contending interrupts are to be serviced. If multiple interrupts occur within the same interrupt level, the interrupt with the lowest vector address is usually processed first. (The relative priorities of multiple interrupts within a single level are fixed in hardware.)

When the CPU grants an interrupt request, interrupt processing starts: All other interrupts are disabled and the program counter value and status flags are pushed to stack. The starting address of the service routine is fetched from the appropriate vector address (plus the next 8-bit value to concatenate the full 16-bit address) and the service routine is executed.

Levels	Vectors	Sources	Reset/Clear
IRQ0	E0H	Timer M0 overflow interrupt	H/W
IRQ0	E2H	Timer M0 capture interrupt	H/W
IRQ1	E4H	Timer M2 interval interrupt	H/W
IRQ2	E6H	Timer M1 overflow interrupt	H/W
IRQ2	E8H	Timer M1 capture interrupt	S/W
IRQ3	EAH	DDC (Multi-master IIC-bus) interrupt	S/W
IRQ4	ECH	P0.0 external interrupt (INT0)	S/W
IRQ5	EEH	P0.1 external interrupt (INT1)	S/W
IRQ6	F0H	P0.2 external interrupt (INT2)	S/W
IRQ7	F2H	Slave only IIC-bus interrupt (note)	S/W

NOTE: Not used for the S3C8647.

Figure 5-2. S3C8639/C863A/C8647 Interrupt Structure

INTERRUPT VECTOR ADDRESSES

All interrupt vector addresses for the S3C8639/C863A/C8647 interrupt structure are stored in the vector address area of the ROM, 00H–FFH (see Figure 5-3). You can allocate unused locations in the vector address area as normal program memory. If you do so, please be careful not to overwrite any of the stored vector addresses. (Table 5-1 lists all vector addresses.)

The program reset address in the ROM is 0100H.
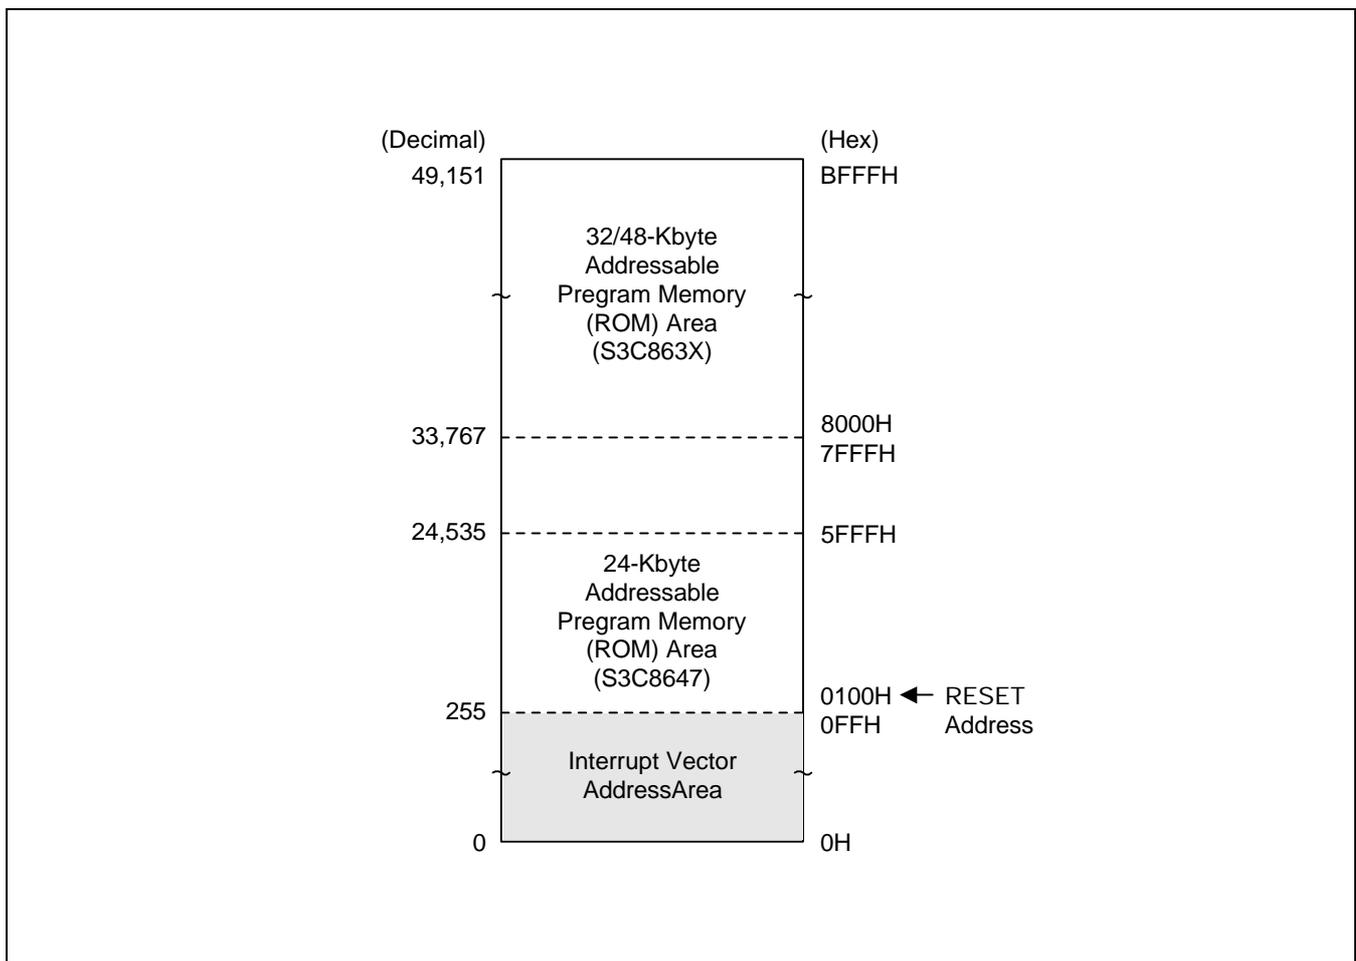

Figure 5-3. ROM Vector Address Area

SAMSUNG
ELECTRONICS

Table 5-1. S3C8639/C863A/C8647 Interrupt Vectors

Vector Address		Interrupt Source	Request		Reset/Clear	
Decimal Value	Hex Value		Interrupt Level	Priority in Level	H/W	S/W
224	E0H	Timer M0 overflow interrupt	IRQ0	0	√	
226	E2H	Timer M0 capture interrupt		1	√	
228	E4H	Timer M2 interval interrupt	IRQ1	–	√	
230	E6H	Timer M1 overflow interrupt	IRQ2	0	√	
232	E8H	Timer M1 capture interrupt		1		√
234	EAH	DDC (Multi-master IIC-bus) interrupt	IRQ3	–		√
236	ECH	P0.0 external interrupt (INT0)	IRQ4	–		√
238	EEH	P0.1 external interrupt (INT1)	IRQ5	–		√
240	F0H	P0.2 external interrupt (INT2)	IRQ6	–		√
242	F2H	Slave only IIC-bus interrupt [3]	IRQ7	–		√

NOTES:

1. Interrupt priorities are identified in inverse order: "0" is the highest priority, "1" is the next highest, and so on.
2. If two or more interrupts within the same level contend, the interrupt with the lowest vector address usually has priority over one with a higher vector address. The priorities within a given level are fixed in hardware.
3. Not used for the S3C8647.

ENABLE/DISABLE INTERRUPT INSTRUCTIONS (EI, DI)

Executing the Enable Interrupts (EI) instruction enables the interrupt structure. All interrupts are then serviced as they occur according to the established priorities.

NOTE

The system initialization routine executed after a reset must always contain an EI instruction (assuming one or more interrupts are used in the application).

During the normal operation, you can execute the DI (Disable Interrupt) instruction at any time to globally disable interrupt processing. The EI and DI instructions change the value of bit 0 in the SYM register. Although you can directly manipulate SYM.0 to enable or disable interrupts, it is recommended that you use the EI and DI instructions instead.

SYSTEM-LEVEL INTERRUPT CONTROL REGISTERS

In addition to the control registers for specific interrupt sources, four system-level registers control interrupt processing:

— The interrupt mask register, IMR, enables (un-masks) or disables (masks) interrupt levels.

— The interrupt priority register, IPR, controls the relative priorities of interrupt levels.

— The interrupt request register, IRQ, contains interrupt pending flags for each interrupt level (as opposed to each interrupt source).

— The system mode register, SYM, enables or disables global interrupt processing. (SYM settings also enable fast interrupts and control the activity of external interface, if implemented.)

Table 5-2. Interrupt Control Register Overview

Control Register	ID	R/W	Function Description
Interrupt mask register	IMR	R/W	Bit settings in the IMR register enable or disable interrupt processing for each of the eight interrupt levels, IRQ0–IRQ7.
Interrupt priority register	IPR	R/W	Controls the relative processing priorities of the interrupt levels. The eight levels are organized into three groups: A, B, and C. Group A is IRQ0 and IRQ1, group B is IRQ2–IRQ4, and group C is IRQ5–IRQ7.
Interrupt request register	IRQ	R	This register contains a request pending bit for each of the seven interrupt levels, IRQ0–IRQ7.
System mode register	SYM	R/W	This register enables and disables dynamic global interrupt processing and fast interrupt processing.

SAMSUNG
ELECTRONICS

INTERRUPT PROCESSING CONTROL POINTS

Interrupt processing can therefore be controlled in two ways: globally or by specific interrupt level and source. Among the system-level control points in the interrupt structure are:

— Global interrupt enabled and disabled (by EI and DI instructions or by direct manipulation of SYM.0)

— Interrupt level enable/disable settings (IMR register)

— Interrupt level priority settings (IPR register)

— Interrupt source enable/disable settings in the corresponding peripheral control registers

NOTE

When writing an application program that handles interrupt processing, be sure to include the necessary register file address (register pointer) information.
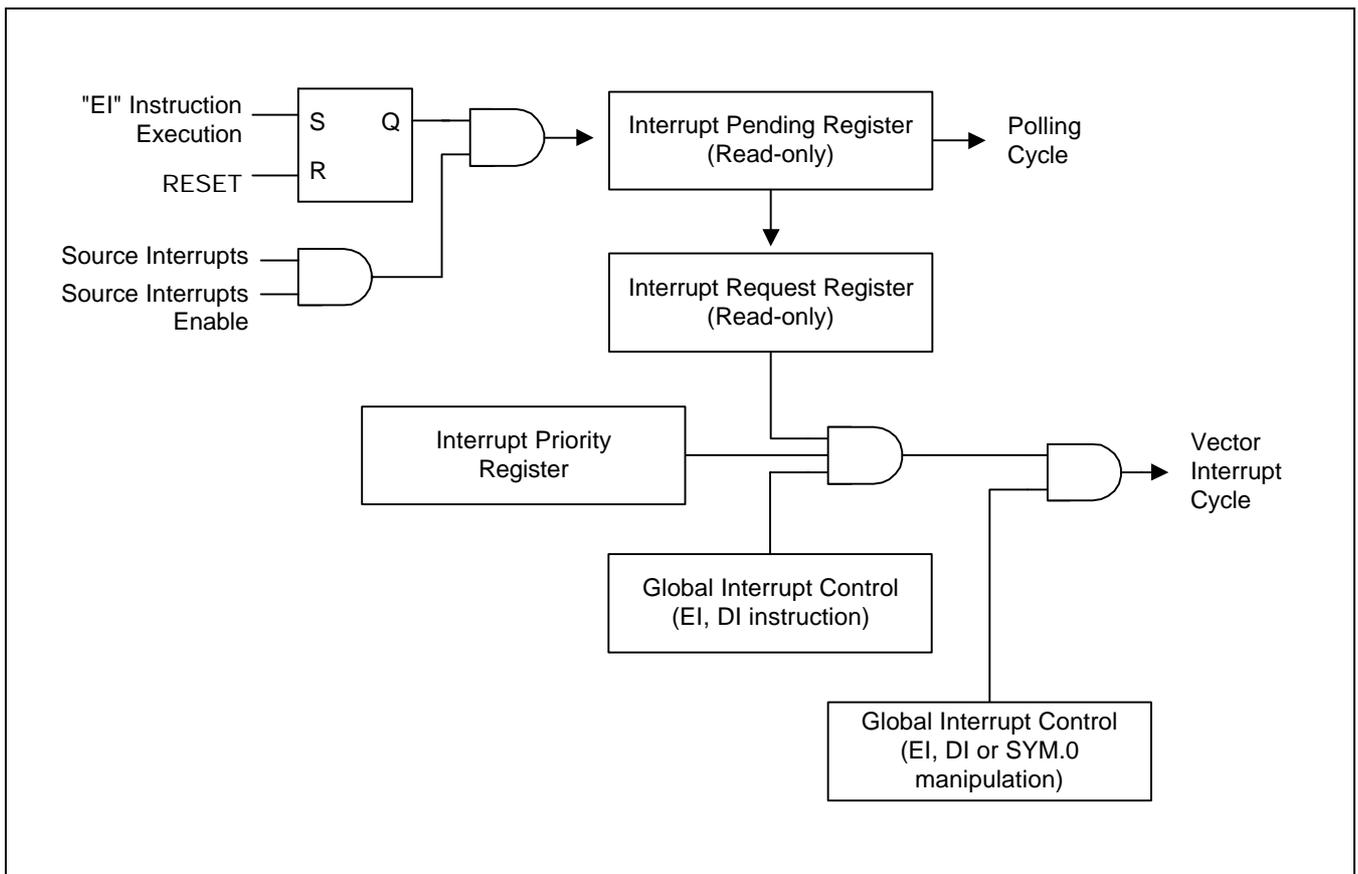

Figure 5-4. Interrupt Function Diagram

PERIPHERAL INTERRUPT CONTROL REGISTERS

For each interrupt source there is a corresponding peripheral control register (or registers) controlling the interrupts generated by the related peripheral. These registers and their locations are listed in Table 5-3.

Table 5-3. Interrupt Source Control Registers

Interrupt Source	Interrupt Level	Control Register(s)	Register Location(s)
Timer M0 overflow interrupt Timer M0 capture interrupt	IRQ0	TM0CON	Set 1, D2H
Timer M2 interval interrupt	IRQ1	TM2CON	Set 1, bank 0, F6H
Timer M1 overflow interrupt Timer M1 capture interrupt	IRQ2	TM1CON	Set 1, bank 0, F5H
DDC (Multi-master IIC-bus) interrupt	IRQ3	DCCR DCSR0	Set 1, bank 1, EBH Set 1, bank 1, ECH
P0.0 external interrupt	IRQ4	P0CONL P0INT	Set 1, bank 0, E5H Set 1, bank 0, EBH
P0.1 external interrupt	IRQ5	P0CONL P0INT	Set 1, bank 0, E5H Set 1, bank 0, EBH
P0.2 external interrupt	IRQ6	P0CONL P0INT	Set 1, bank 0, E5H Set 1, bank 0, EBH
Slave only IIC-bus interrupt [note]	IRQ7	SICSR	Set 1, bank 1, F2H

NOTE: Not used for the S3C8647.

SYSTEM MODE REGISTER (SYM)

The system mode register, SYM (set 1, DEH), is used to globally enable and disable interrupt processing and to control fast interrupt processing. Figure 5-5 shows the effect of the various control settings.

A reset clears SYM.7, SYM.1, and SYM.0 to "0". Other SYM bit values (for fast interrupt level selection) are undetermined.

The instructions EI and DI enable and disable global interrupt processing, respectively, by modifying the bit 0 value of the SYM register. In order to enable interrupt processing an Enable Interrupt (EI) instruction must be included in the initialization routine, which follows a reset operation. Although you can manipulate SYM.0 directly to enable and disable interrupts during the normal operation, it is recommended to use the EI and DI instructions for this purpose.

0	1	0	IRQ2
0	1	1	IRQ3
1	0	0	IRQ4
1	0	1	IRQ5
1	1	0	IRQ6
1	1	1	IRQ7 (note)

NOTE: Not used for the S3C8647.

Figure 5-5. System Mode Register (SYM)

INTERRUPT MASK REGISTER (IMR)

The interrupt mask register, IMR (set 1, DDH) is used to enable or disable interrupt processing for individual interrupt levels. After a reset, all IMR bit values are undetermined and must therefore be written to their required settings by the initialization routine.

Each IMR bit corresponds to a specific interrupt level: bit 1 to IRQ1, bit 2 to IRQ2, and so on. When the IMR bit of an interrupt level is cleared to "0", interrupt processing for that level is disabled (masked). When you set a level's IMR bit to "1", interrupt processing for the level is enabled (not masked).

The IMR register is mapped to register location DDH in set 1. Bit values can be read and written by instructions using the Register addressing mode.

1 = Enable (un-mask)interrupt level

NOTE: Not used for the S3C8647.

Figure 5-6. Interrupt Mask Register (IMR)

INTERRUPT PRIORITY REGISTER (IPR)

The interrupt priority register, IPR (set 1, bank 0, FFH), is used to set the relative priorities of the interrupt levels in the microcontroller's interrupt structure. After a reset, all IPR bit values are undetermined and must therefore be written to their required settings by the initialization routine.

When more than one interrupt sources are active, the source with the highest priority is serviced first. If two sources belong to the same interrupt level, the source with the lower vector address usually has priority. (This priority is fixed in hardware.)

To support programming of the relative interrupt level priorities, they are organized into groups and subgroups by the interrupt logic. Please note that these groups (and subgroups) are used only by IPR logic for the IPR register priority definitions (see Figure 5-7):

    Group A   IRQ0, IRQ1

    Group B   IRQ2, IRQ3, IRQ4

    Group C   IRQ5, IRQ6, IRQ7
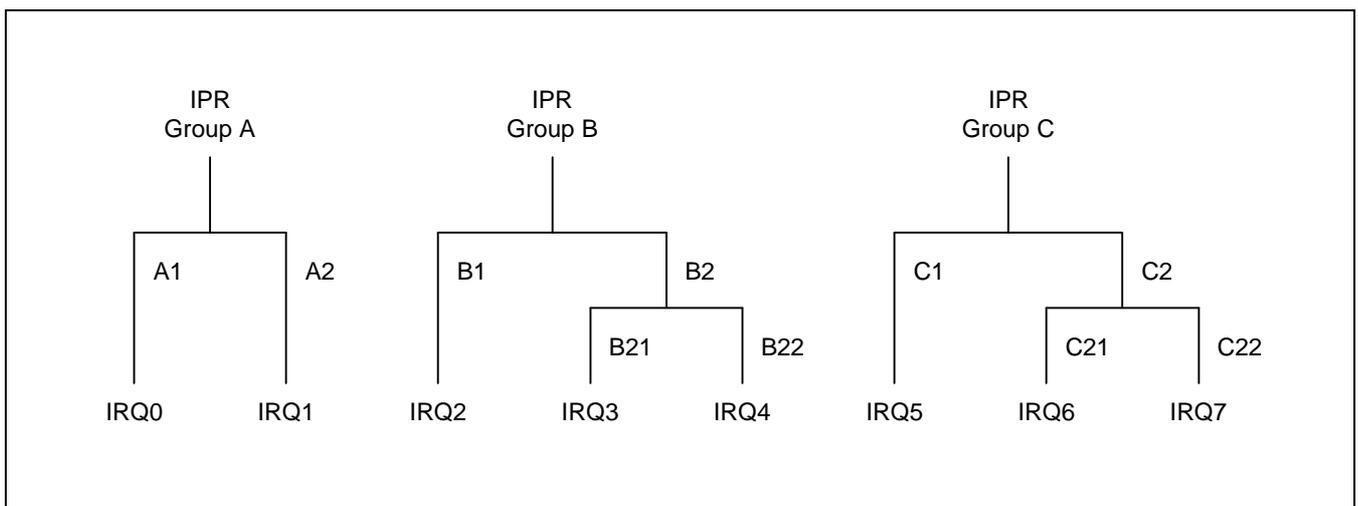

Figure 5-7. Interrupt Request Priority Groups

As you can see in Figure 5-8, IPR.7, IPR.4, and IPR.1 control the relative priority of interrupt groups A, B, and C. For example, the setting "001B" for these bits would select the group relationship B > C > A. The setting "101B" would select the relationship C > B > A.

The functions of the other IPR bit settings are as follows:

— Interrupt group C includes a sub group that has an additional priority relationship among interrupt levels 5, 6, and 7. IPR.6 defines the subgroup C relationship.

— IPR.5 controls the relative priorities of group C interrupts.

— Interrupt group B includes a subgroup that has an additional priority relationship among interrupt levels 2, 3, and 4. IPR.3 defines the subgroup B relationship.

— IPR.2 controls interrupt group B.

— IPR.0 controls the relative priority setting of IRQ0 and IRQ1 interrupts.

ELECTRONICS

INTERRUPT REQUEST REGISTER (IRQ)

You can poll bit values in the interrupt request register, IRQ (set 1, DCH), to monitor interrupt request status for all levels in the microcontroller's interrupt structure. Each bit corresponds to the interrupt level of the same number: bit 0 to IRQ0, bit 1 to IRQ1, and so on. A "0" indicates that no interrupt request is currently being issued for that level. A "1" indicates that an interrupt request has been generated for that level.

IRQ bit values are addressable in read-only using Register addressing mode. You can read (test) the contents of the IRQ register at any time using bit or byte addressing to determine the current interrupt request status of specific interrupt levels. After a reset, all IRQ status bits are cleared to "0".

You can poll IRQ register values even if a DI instruction has been executed (that is, if global interrupt processing is disabled). If an interrupt occurs while the interrupt structure is disabled, the CPU will not service it. You can, however, still detect the interrupt request by polling the IRQ register. In this way, you can determine which events occurred while the interrupt structure was globally disabled.

Figure 5-9. Interrupt Request Register (IRQ)
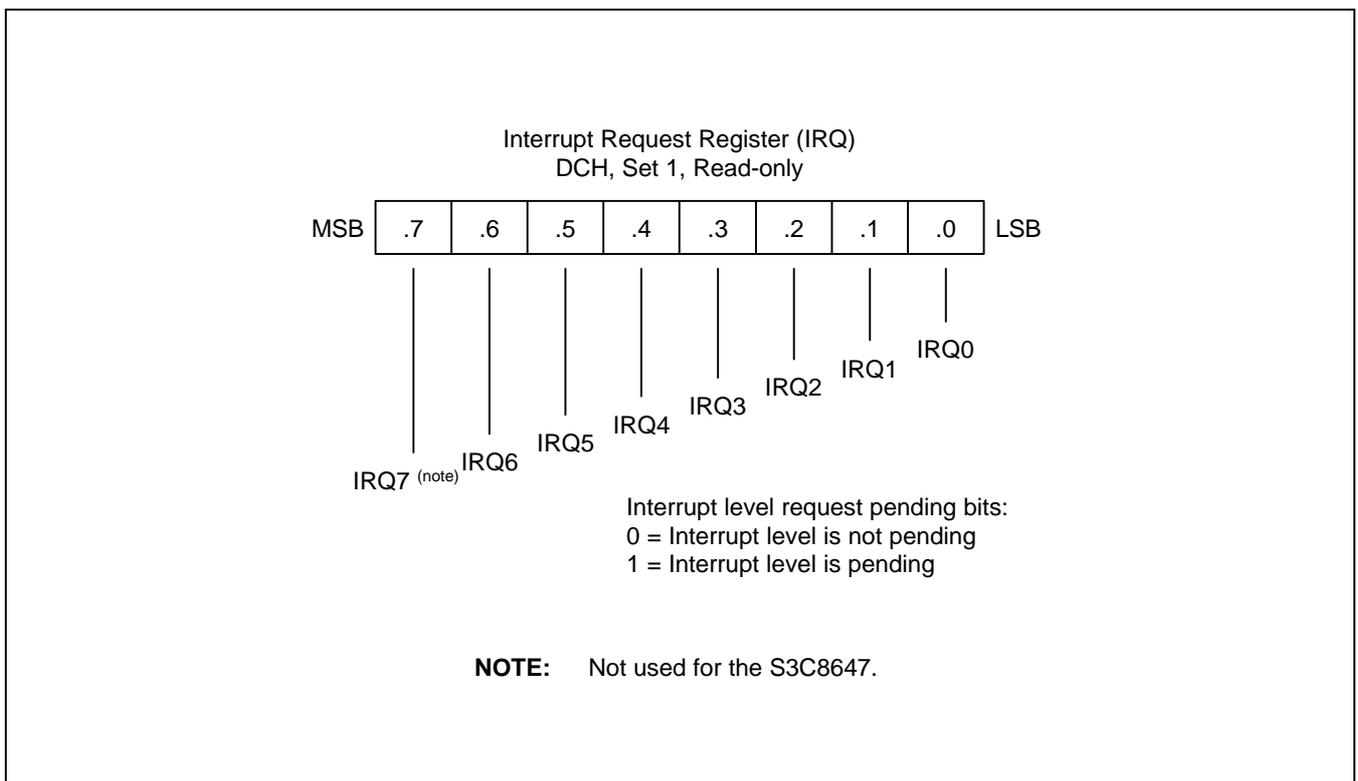

INTERRUPT PENDING FUNCTION TYPES

Overview

There are two types of interrupt pending bits: One type that is automatically cleared by hardware after the interrupt service routine is acknowledged and executed; the other that must be cleared by the application program's interrupt service routine.

Pending Bits Cleared Automatically by Hardware

For interrupt pending bits that are cleared automatically by hardware, interrupt logic sets the corresponding pending bit to "1" when a request occurs. It then issues an IRQ pulse to inform the CPU that an interrupt is waiting to be serviced. The CPU acknowledges the interrupt source, executes the service routine, and clears the pending bit to "0". This type of pending bit is not mapped and cannot, therefore, be read or written by application software.

In the S3C8639/C863A/C8647 interrupt structure, the timer M0 overflow interrupt (IRQ0, vector E0H), the timer M0 capture interrupt (IRQ0, vector E2H), the timer M2 interval interrupt (IRQ1, vector E4H), and the timer M1 overflow interrupt (IRQ2, vector E6H) belong to this category of interrupts in which pending conditions are cleared automatically by hardware.

Pending Bits Cleared by the Service Routine

The second type of pending bit is the one that should be cleared by program software. The service routine must clear the appropriate pending bit before a return-from-interrupt subroutine (IRET) occurs. To do this, a "0" must be written to the corresponding pending bit location in the source's mode or control register.

In the S3C8639/C863A/C8647 interrupt structure, pending conditions for all interrupt sources, *except* the timer M0 overflow/capture, the timer M2 interval interrupt and the timer M1 overflow interrupt, must be cleared by the program software's interrupt service routine.

INTERRUPT SOURCE POLLING SEQUENCE

The interrupt request polling and servicing sequence is as follows:

1. A source generates an interrupt request by setting the interrupt request bit to "1".
2. The CPU polling procedure identifies a pending condition for that source.
3. The CPU checks the source's interrupt level.
4. The CPU generates an interrupt acknowledge signal.
5. Interrupt logic determines the interrupt's vector address.
6. The service routine starts and the source's pending bit is cleared to "0" (by hardware or by software).
7. The CPU continues polling for interrupt requests.

INTERRUPT SERVICE ROUTINES

Before an interrupt request is serviced, the following conditions must be met:

— Interrupt processing must be globally enabled (EI, SYM.0 = "1")
— The interrupt level must be enabled (IMR register)
— The interrupt level must have the highest priority if more than one levels are currently requesting service
— The interrupt must be enabled at the interrupt's source (peripheral control register)

When all of the above conditions are met, the interrupt request is acknowledged at the end of the instruction cycle. The CPU then initiates an interrupt machine cycle that completes the following processing sequence:

1. Reset (clear to "0") the interrupt enable bit in the SYM register (SYM.0) to disable all subsequent interrupts.
2. Save the program counter (PC) and status flags to the system stack.
3. Branch to the interrupt vector to fetch the address of the service routine.
4. Pass control to the interrupt service routine.

When the interrupt service routine is completed, the CPU issues an Interrupt Return (IRET). The IRET restores the PC and status flags, setting SYM.0 to "1". It allows the CPU to process the next interrupt request.

GENERATING INTERRUPT VECTOR ADDRESSES

The interrupt vector area in the ROM (00H–FFH) contains the addresses of interrupt service routines that correspond to each level in the interrupt structure. Vectored interrupt processing follows this sequence:

1. Push the program counter's low-byte value to the stack.

2. Push the program counter's high-byte value to the stack.

3. Push the FLAG register values to the stack.

4. Fetch the service routine's high-byte address from the vector location.

5. Fetch the service routine's low-byte address from the vector location.

6. Branch to the service routine specified by the concatenated 16-bit vector address.

NOTE

A 16-bit vector address always begins at an even-numbered ROM address within the range of 00H–FFH.

NESTING OF VECTORED INTERRUPTS

It is possible to nest a higher-priority interrupt request while a lower-priority request is being serviced. To do this, you must follow these steps:

1. Push the current 8-bit interrupt mask register (IMR) value to the stack (PUSH IMR).

2. Load the IMR register with a new mask value that enables only the higher priority interrupt.

3. Execute an EI instruction to enable interrupt processing (a higher priority interrupt will be processed if it occurs).

4. When the lower-priority interrupt service routine ends, restore the IMR to its original value by returning the previous mask value from the stack (POP IMR).

5. Execute an IRET.

Depending on the application, you may be able to simplify the above procedure to some extent.

INSTRUCTION POINTER (IP)

The instruction pointer (IP) is adopted by all the S3C8-series microcontrollers to control the optional high-speed interrupt processing feature called *fast interrupts*. The IP consists of register pair DAH and DBH. The names IP of registers are IPH (high byte, IP15–IP8) and IPL (low byte, IP7–IP0).

SAMSUNG
ELECTRONICS

FAST INTERRUPT PROCESSING

The feature called *fast interrupt processing* allows an interrupt within a given level to be completed in approximately six clock cycles rather than the usual 10 clock cycles. SYM.4–SYM.2 are used to select a specific interrupt level for fast processing and SYM.1 enables or disables fast interrupt processing.

Two other system registers support fast interrupt processing:

— The instruction pointer (IP) contains the starting address of the service routine (and is later used to swap the program counter values), and

— When a fast interrupt occurs, the contents of the FLAGS register is stored in an unmapped, dedicated register called FLAGS' ("FLAGS prime").

NOTES

1. For the S3C8639/C863A/C8647 microcontrollers, the service routine for any of the seven interrupt levels (IRQ0–IRQ7) can be selected for fast interrupt processing.
   The S3C8647 microcontroller has six interrupt levels (IRQ0-IRQ6) for fast interrupt processing.

2. When you use a fast interrupt in a multi-source interrupt vector, the fast interrupt may not be processed if you use two sources as interrupt vector in normal mode. But it is possible when you use only one source as interrupt vector.

Procedure for Initiating Fast Interrupts

To initiate fast interrupt processing, follow these steps:

1. Load the start address of the service routine into the instruction pointer (IP).

2. Load the interrupt level number (IRQn) into the fast interrupt selection field (SYM.4–SYM.2)

3. Write a "1" to the fast interrupt enable bit in the SYM register.

Fast Interrupt Service Routine

When an interrupt occurs in the level selected for fast interrupt processing, the following events occur:

1. The contents of the instruction pointer and the PC are swapped.

2. The FLAG register values are written to the FLAGS' ("FLAGS prime") register.

3. The fast interrupt status bit in the FLAGS register is set.

4. The interrupt is serviced.

5. Assuming that the fast interrupt status bit is set, when the fast interrupt service routine ends, the instruction pointer and PC values are swapped back.

6. The content of FLAGS' ("FLAGS prime") is copied automatically back to the FLAGS register.

7. The fast interrupt status bit in FLAGS is cleared automatically.

Relationship to Interrupt Pending Bit Types

As described previously, there are two types of interrupt pending bits: One is the type that is automatically cleared by hardware after the interrupt service routine is acknowledged and executed, and the other is the one that must be cleared by the application program's interrupt service routine. You can select fast interrupt processing for interrupts with either type of pending condition clear function — by hardware or by software.

Programming Guidelines

Remember that the only way to enable/disable a fast interrupt is to set/clear the fast interrupt enable bit in the SYM register, SYM.1. Executing an EI or DI instruction globally enables or disables all interrupt processing, including fast interrupts.

NOTE

If you use fast interrupts, remember to load the IP with a new start address when the fast interrupt service routine ends.

☞   **PROGRAMMING TIP — Setting Up the Interrupt Control Structure**

This example shows you how to enable interrupts for select interrupt sources, disable interrupts for other sources, and set interrupt priorities for the S3C8639/C863A/C8647 interrupt structure. The following is a sample program:

— Disables the watchdog function.

— Enables the following interrupts: P0.0 external interrupt, timer M0 capture/overflow, timer M1 capture/overflow, timer M2 interval interrupt, and DDC interrupt.

— Disables the following interrupts: P0.1 and P0.2 external interrupts, and slave only IIC-bus interrupt.

— Sets interrupt priorities as P0.0 > timer M2 > timer M0 > timer M1 > DDC.

```

          LD        IPR,#1EH                     ; IRQ4 > IRQ0 > IRQ1 > IRQ2 > IRQ3
                                                 ; (P0.0 > timer M0 > timer M2 > timer M1 > DDC)
          EI                                     ; Enable interrupts globally
          •
          •
          •
```

SAMSUNG
ELECTRONICS

☞   **PROGRAMMING TIP — Programming Level IRQ0 as a Fast Interrupt**

The following example shows you how to program fast interrupt processing for a selected interrupt level — in this case, for the timer M0 capture interrupt:

```
        •
        •
        •
        LD      TM0CON,#8FH         ;   Enable TM0OVF interrupt
                                    ;   Enable TM0CAP interrupt
                                    ;   Capture mode (on rising signal edges)
                                    ;   Select f_OSC/8 as the T0 clock source
        LD      P0CONH,#01H         ;   Set P0.4 to capture input mode
        LDW     IPH,#T0_INT         ;   IPH ← high byte of interrupt service routine
                                    ;   IPL ← low byte of interrupt service routine
        LD      SYM,#02H            ;   Enable fast interrupt processing
                                    ;   Select IRQ0 for fast interrupt service
        EI                          ;   Enable interrupts
        •
        •
        •

FAST_RET: IRET                      ;   IP ← Address of T0_INT (again)
T0_INT:
        •
        •
        •
        (Fast service routine executes)
        •
        •
        •
        LD      TM0CON,#8FH         ;   Clear TM0INT interrupt pending bit
        JP      T,FAST_RET
```

NOTES

6 INSTRUCTION SET

OVERVIEW

The SAM8RC instruction set is specifically designed to support the large register files that are typical of most SAM8RC microcontrollers. There are 78 instructions. The powerful data manipulation capabilities and features of the instruction set include:

— A full complement of 8-bit arithmetic and logic operations, including multiply and divide

— No special I/O instructions (I/O control/data registers are mapped directly into the register file)

— Decimal adjustment included in binary-coded decimal (BCD) operations

— 16-bit (word) data can be incremented and decremented

— Flexible instructions for bit addressing, rotate, and shift operations

DATA TYPES

The SAM8RC CPU performs operations on bits, bytes, BCD digits, and two-byte words. Bits in the register file can be set, cleared, complemented, and tested. Bits within a byte are numbered from 7 to 0, where bit 0 is the least significant (right-most) bit.

REGISTER ADDRESSING

To access an individual register, an 8-bit address in the range 0-255 or the 4-bit address of a working register is specified. Paired registers can be used to construct 16-bit data or 16-bit program memory or data memory addresses. For detailed information about register addressing, please refer to Section 2, "Address Spaces."

ADDRESSING MODES

There are seven explicit addressing modes: Register (R), Indirect Register (IR), Indexed (X), Direct (DA), Relative (RA), Immediate (IM), and Indirect (IA). For detailed descriptions of these addressing modes, please refer to Section 3, "Addressing Modes."

Mnemonic	Operands	Instruction

Rotate and Shift Instructions

RL	dst	Rotate left
RLC	dst	Rotate left through carry
RR	dst	Rotate right
RRC	dst	Rotate right through carry
SRA	dst	Shift right arithmetic
SWAP	dst	Swap nibbles

CPU Control Instructions

CCF		Complement carry flag
DI		Disable interrupts
EI		Enable interrupts
IDLE		Enter Idle mode
NOP		No operation
RCF		Reset carry flag
SB0		Set bank 0
SB1		Set bank 1
SCF		Set carry flag
SRP	src	Set register pointers
SRP0	src	Set register pointer 0
SRP1	src	Set register pointer 1
STOP		Enter Stop mode

FLAGS REGISTER (FLAGS)

The flags register FLAGS contains eight bits that describe the current status of CPU operations. Four of these bits, FLAGS.7–FLAGS.4, can be tested and used with conditional jump instructions; two others FLAGS.3 and FLAGS.2 are used for BCD arithmetic.

The FLAGS register also contains a bit to indicate the status of fast interrupt processing (FLAGS.1) and a bank address status bit (FLAGS.0) to indicate whether bank 0 or bank 1 is currently being addressed. FLAGS register can be set or reset by instructions as long as its outcome does not affect the flags, such as, Load instruction.

Logical and Arithmetic instructions such as, AND, OR, XOR, ADD, and SUB can affect the Flags register. For example, the AND instruction updates the Zero, Sign and Overflow flags based on the outcome of the AND instruction. If the AND instruction uses the Flags register as the destination, then simultaneously, two write will occur to the Flags register producing an unpredictable result.
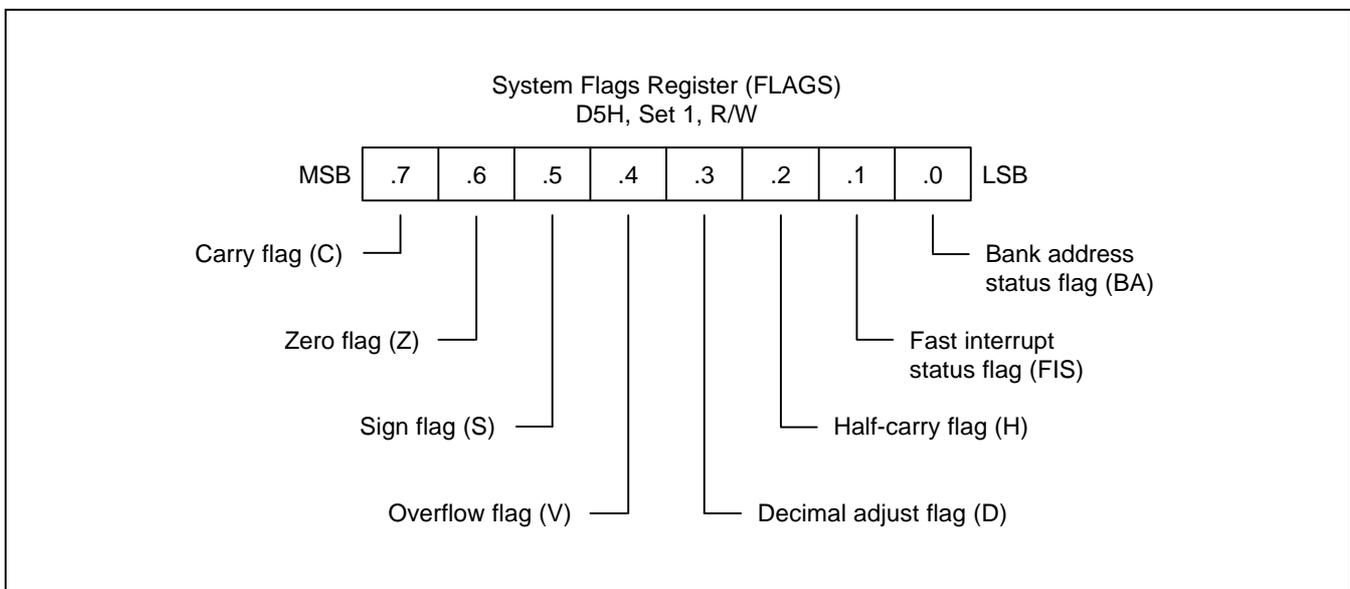

Figure 6-1. System Flags Register (FLAGS)

FLAG DESCRIPTIONS

C   Carry Flag (FLAGS.7)

The C flag is set to "1" if the result from an arithmetic operation generates a carry-out from or a borrow to the bit 7 position (MSB). After rotate and shift operations, it contains the last value shifted out of the specified register. Program instructions can set, clear, or complement the carry flag.

Z   Zero Flag (FLAGS.6)

For arithmetic and logic operations, the Z flag is set to "1" if the result of the operation is zero. For operations that test register bits, and for shift and rotate operations, the Z flag is set to "1" if the result is logic zero.

S   Sign Flag (FLAGS.5)

Following arithmetic, logic, rotate, or shift operations, the sign bit identifies the state of the MSB of the result. A logic zero indicates a positive number and a logic one indicates a negative number.

V   Overflow Flag (FLAGS.4)

The V flag is set to "1" when the result of a two's-complement operation is greater than + 127 or less than – 128. It is also cleared to "0" following logic operations.

D   Decimal Adjust Flag (FLAGS.3)

The DA bit is used to specify what type of instruction was executed last during BCD operations, so that a subsequent decimal adjust operation can execute correctly. The DA bit is not usually accessed by programmers, and cannot be used as a test condition.

H   Half-Carry Flag (FLAGS.2)

The H bit is set to "1" whenever an addition generates a carry-out of bit 3, or when a subtraction borrows out of bit 4. It is used by the Decimal Adjust (DA) instruction to convert the binary result of a previous addition or subtraction into the correct decimal (BCD) result. The H flag is seldom accessed directly by a program.

FIS   Fast Interrupt Status Flag (FLAGS.1)

The FIS bit is set during a fast interrupt cycle and reset during the IRET following interrupt servicing. When set, it inhibits all interrupts and causes the fast interrupt return to be executed when the IRET instruction is executed.

BA   Bank Address Flag (FLAGS.0)

The BA flag indicates which register bank in the set 1 area of the internal register file is currently selected, bank 0 or bank 1. The BA flag is cleared to "0" (select bank 0) when you execute the SB0 instruction and is set to "1" (select bank 1) when you execute the SB1 instruction.

INSTRUCTION SET NOTATION

Table 6-2. Flag Notation Conventions

Flag	Description
C	Carry flag
Z	Zero flag
S	Sign flag
V	Overflow flag
D	Decimal-adjust flag
H	Half-carry flag
0	Cleared to logic zero
1	Set to logic one
*	Set or cleared according to operation
–	Value is unaffected
x	Value is undefined

Table 6-3. Instruction Set Symbols

Symbol	Description
dst	Destination operand
src	Source operand
@	Indirect register address prefix
PC	Program counter
IP	Instruction pointer
FLAGS	Flags register (D5H)
RP	Register pointer
#	Immediate operand or register address prefix
H	Hexadecimal number suffix
D	Decimal number suffix
B	Binary number suffix
opc	Opcode

The table header reads: OPCODE MAP / LOWER NIBBLE (HEX)

CONDITION CODES

The opcode of a conditional jump always contains a 4-bit field called the condition code (cc). This specifies under which conditions it is to execute the jump. For example, a conditional jump with the condition code for "equal" after a compare operation only jumps if the two operands are equal. Condition codes are listed in Table 6-6.

The carry (C), zero (Z), sign (S), and overflow (V) flags are used to control the operation of conditional jump instructions.

Table 6-6. Condition Codes

Binary	Mnemonic	Description	Flags Set
0000	F	Always false	–
1000	T	Always true	–
0111 (note)	C	Carry	C = 1
1111 (note)	NC	No carry	C = 0
0110 (note)	Z	Zero	Z = 1
1110 (note)	NZ	Not zero	Z = 0
1101	PL	Plus	S = 0
0101	MI	Minus	S = 1
0100	OV	Overflow	V = 1
1100	NOV	No overflow	V = 0
0110 (note)	EQ	Equal	Z = 1
1110 (note)	NE	Not equal	Z = 0
1001	GE	Greater than or equal	(S XOR V) = 0
0001	LT	Less than	(S XOR V) = 1
1010	GT	Greater than	(Z OR (S XOR V)) = 0
0010	LE	Less than or equal	(Z OR (S XOR V)) = 1
1111 (note)	UGE	Unsigned greater than or equal	C = 0
0111 (note)	ULT	Unsigned less than	C = 1
1011	UGT	Unsigned greater than	(C = 0 AND Z = 0) = 1
0011	ULE	Unsigned less than or equal	(C OR Z) = 1

NOTES:
1. It indicates condition codes that are related to two different mnemonics but which test the same flag. For example, Z and EQ are both true if the zero flag (Z) is set, but after an ADD instruction, Z would probably be used; after a CP instruction, however, EQ would probably be used.
2. For operations involving unsigned numbers, the special condition codes UGE, ULT, UGT, and ULE must be used.

INSTRUCTION DESCRIPTIONS

This section contains detailed information and programming examples for each instruction in the SAM8RC instruction set. Information is arranged in a consistent format for improved readability and for fast referencing. The following information is included in each instruction description:

— Instruction name (mnemonic)

— Full instruction name

— Source/destination format of the instruction operand

— Shorthand notation of the instruction's operation

— Textual description of the instruction's effect

— Specific flag settings affected by the instruction

— Detailed description of the instruction's format, execution time, and addressing mode(s)

— Programming example(s) explaining how to use the instruction

ADC — Add with carry

ADC   dst,src

Operation: dst ← dst + src + c

The source operand, along with the setting of the carry flag, is added to the destination operand and the sum is stored in the destination. The contents of the source are unaffected. Two's-complement addition is performed. In multiple precision arithmetic, this instruction permits the carry from the addition of low-order operands to be carried into the addition of high-order operands.

Flags:

C: Set if there is a carry from the most significant bit of the result; cleared otherwise.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurs, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise.
D: Always cleared to "0".
H: Set if there is a carry from the most significant bit of the low-order four bits of the result; cleared otherwise.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src		2	4	12	r	r
				6	13	r	lr
opc	src	dst	3	6	14	R	R
				6	15	R	IR
opc	dst	src	3	6	16	R	IM

Example: Given: R1 = 10H, R2 = 03H, C flag = "1", register 01H = 20H, register 02H = 03H, and register 03H = 0AH:

ADC	R1,R2	→	R1 = 14H, R2 = 03H
ADC	R1,@R2	→	R1 = 1BH, R2 = 03H
ADC	01H,02H	→	Register 01H = 24H, register 02H = 03H
ADC	01H,@02H	→	Register 01H = 2BH, register 02H = 03H
ADC	01H,#11H	→	Register 01H = 32H

In the first example, destination register R1 contains the value 10H, the carry flag is set to "1", and the source working register R2 contains the value 03H. The statement "ADC R1,R2" adds 03H and the carry flag value ("1") to the destination value 10H, leaving 14H in register R1.

SAMSUNG
ELECTRONICS

ADD — Add

ADD   dst,src

Operation: dst ← dst + src

The source operand is added to the destination operand and the sum is stored in the destination. The contents of the source are unaffected. Two's-complement addition is performed.

Flags: **C:** Set if there is a carry from the most significant bit of the result; cleared otherwise.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise.
D: Always cleared to "0".
H: Set if a carry from the low-order nibble occurred.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src		2	4	02	r	r
				6	03	r	Ir
opc	src	dst	3	6	04	R	R
				6	05	R	IR
opc	dst	src	3	6	06	R	IM

Example: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

ADD   R1,R2   →   R1 = 15H, R2 = 03H
ADD   R1,@R2   →   R1 = 1CH, R2 = 03H
ADD   01H,02H   →   Register 01H = 24H, register 02H = 03H
ADD   01H,@02H   →   Register 01H = 2BH, register 02H = 03H
ADD   01H,#25H   →   Register 01H = 46H

In the first example, destination working register R1 contains 12H and the source working register R2 contains 03H. The statement "ADD R1,R2" adds 03H to 12H, leaving the value 15H in register R1.

AND — Logical AND

AND   dst,src

Operation: dst ← dst AND src

The source operand is logically ANDed with the destination operand. The result is stored in the destination. The AND operation results in a "1" bit being stored whenever the corresponding bits in the two operands are both logic ones; otherwise a "0" bit value is stored. The contents of the source are unaffected.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Always cleared to "0".
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src		2	4	52	r	r
				6	53	r	lr
opc	src	dst	3	6	54	R	R
				6	55	R	IR
opc	dst	src	3	6	56	R	IM

Example: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

AND   R1,R2   →   R1 = 02H, R2 = 03H

AND   R1,@R2   →   R1 = 02H, R2 = 03H

AND   01H,02H   →   Register 01H = 01H, register 02H = 03H

AND   01H,@02H   →   Register 01H = 00H, register 02H = 03H

AND   01H,#25H   →   Register 01H = 21H

In the first example, destination working register R1 contains the value 12H and the source working register R2 contains 03H. The statement "AND R1,R2" logically ANDs the source operand 03H with the destination operand value 12H, leaving the value 02H in register R1.

SAMSUNG
ELECTRONICS

BAND — Bit AND

BAND   dst,src.b

BAND   dst.b,src

Operation: dst(0) ← dst(0) AND src(b)

                        or

dst(b) ← dst(b) AND src(0)

The specified bit of the source (or the destination) is logically ANDed with the zero bit (LSB) of the destination (or source). The resultant bit is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: **C:** Unaffected.
                 Z: Set if the result is "0"; cleared otherwise.
                 S: Cleared to "0".
                 V: Undefined.
                 D: Unaffected.
                 H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | b | 0	src	3	6	67	r0	Rb
opc	src | b | 1	dst	3	6	67	Rb	r0

NOTE: In the second byte of the 3-byte instruction formats, the destination (or source) address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H and register 01H = 05H:

BAND   R1,01H.1   →   R1 = 06H, register 01H = 05H
BAND   01H.1,R1   →   Register 01H = 05H, R1 = 07H

In the first example, source register 01H contains the value 05H (00000101B) and destination working register R1 contains 07H (00000111B). The statement "BAND R1,01H.1" ANDs the bit 1 value of the source register ("0") with the bit 0 value of register R1 (destination), leaving the value 06H (00000110B) in register R1.

SAMSUNG

ELECTRONICS

BCP — Bit Compare

BCP dst,src.b

Operation: dst(0) – src(b)

The specified bit of the source is compared to (subtracted from) bit zero (LSB) of the destination. The zero flag is set if the bits are the same; otherwise it is cleared. The contents of both operands are unaffected by the comparison.

Flags: **C:** Unaffected.
Z: Set if the two bits are the same; cleared otherwise.
S: Cleared to "0".
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | b | 0	src	3	6	17	r0	Rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H and register 01H = 01H:

BCP R1,01H.1 → R1 = 07H, register 01H = 01H

If destination working register R1 contains the value 07H (00000111B) and the source register 01H contains the value 01H (00000001B), the statement "BCP R1,01H.1" compares bit one of the source register (01H) and bit zero of the destination register (R1). Because the bit values are not identical, the zero flag bit (Z) is cleared in the FLAGS register (0D5H).

SAMSUNG
ELECTRONICS

BITC — Bit Complement

BITC   dst.b

Operation: dst(b) ← NOT dst(b)

This instruction complements the specified bit within the destination without affecting any other bits in the destination.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Cleared to "0".
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc | dst | b | 0	2	4	57	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H

BITC   R1.1   →   R1 = 05H

If working register R1 contains the value 07H (00000111B), the statement "BITC R1.1" complements bit one of the destination and leaves the value 05H (00000101B) in register R1. Because the result of the complement is not "0", the zero flag (Z) in the FLAGS register (0D5H) is cleared.

BITR — Bit Reset

BITR   dst.b

Operation: dst(b) ← 0

The BITR instruction clears the specified bit within the destination without affecting any other bits in the destination.

Flags: No flags are affected.

Format:

		Bytes	**Cycles**	**Opcode (Hex)**	**Addr Mode dst**
opc	dst | b | 0	2	4	77	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BITR   R1.1   →   R1 = 05H

If the value of working register R1 is 07H (00000111B), the statement "BITR R1.1" clears bit one of the destination register R1, leaving the value 05H (00000101B).

SAMSUNG
ELECTRONICS

BITS — Bit Set

BITS   dst.b

Operation: dst(b) ← 1

The BITS instruction sets the specified bit within the destination without affecting any other bits in the destination.

Flags: No flags are affected.

Format:

			Bytes	**Cycles**	**Opcode (Hex)**	**Addr Mode** <u>dst</u>
opc	dst | b | 1		2	4	77	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BITS   R1.3   →   R1 = 0FH

If working register R1 contains the value 07H (00000111B), the statement "BITS R1.3" sets bit three of the destination register R1 to "1", leaving the value 0FH (00001111B).

BOR — Bit OR

BOR	dst,src.b
BOR	dst.b,src

Operation: dst(0) ← dst(0) OR src(b)

or

dst(b) ← dst(b) OR src(0)

The specified bit of the source (or the destination) is logically ORed with bit zero (LSB) of the destination (or the source). The resulting bit value is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags:
- **C:** Unaffected.
- **Z:** Set if the result is "0"; cleared otherwise.
- **S:** Cleared to "0".
- **V:** Undefined.
- **D:** Unaffected.
- **H:** Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | b | 0	src	3	6	07	r0	Rb
opc	src | b | 1	dst	3	6	07	Rb	r0

NOTE: In the second byte of the 3-byte instruction formats, the destination (or source) address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit.

Example: Given: R1 = 07H and register 01H = 03H:

BOR	R1, 01H.1	→	R1 = 07H, register 01H = 03H
BOR	01H.2, R1	→	Register 01H = 07H, R1 = 07H

In the first example, destination working register R1 contains the value 07H (00000111B) and source register 01H the value 03H (00000011B). The statement "BOR R1,01H.1" logically ORs bit one of register 01H (source) with bit zero of R1 (destination). This leaves the same value (07H) in working register R1.

In the second example, destination register 01H contains the value 03H (00000011B) and the source working register R1 the value 07H (00000111B). The statement "BOR 01H.2,R1" logically ORs bit two of register 01H (destination) with bit zero of R1 (source). This leaves the value 07H in register 01H.

SAMSUNG
ELECTRONICS

BTJRF — Bit Test, Jump Relative on False

BTJRF   dst,src.b

Operation: If src(b) is a "0", then PC ← PC + dst

The specified bit within the source operand is tested. If it is a "0", the relative address is added to the program counter and control passes to the statement whose address is now in the PC; otherwise, the instruction following the BTJRF instruction is executed.

Flags: No flags are affected.

Format:

	(Note 1)		**Bytes**	**Cycles**	**Opcode (Hex)**	**Addr Mode**	
						dst	**src**
opc	src | b | 0	dst	3	10	37	RA	rb

NOTE: In the second byte of the instruction format, the source address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BTJRF   SKIP,R1.3   →   PC jumps to SKIP location

If working register R1 contains the value 07H (00000111B), the statement "BTJRF SKIP,R1.3" tests bit 3. Because it is "0", the relative address is added to the PC and the PC jumps to the memory location pointed to by the SKIP. (Remember that the memory location must be within the allowed range of + 127 to − 128.)

BTJRT — Bit Test, Jump Relative on True

BTJRT   dst,src.b

Operation: If src(b) is a "1", then PC ← PC + dst

The specified bit within the source operand is tested. If it is a "1", the relative address is added to the program counter and control passes to the statement whose address is now in the PC; otherwise, the instruction following the BTJRT instruction is executed.

Flags: No flags are affected.

Format:

(Note 1)			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src | b | 1	dst	3	10	37	RA	rb

NOTE: In the second byte of the instruction format, the source address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BTJRT   SKIP,R1.1

If working register R1 contains the value 07H (00000111B), the statement "BTJRT SKIP,R1.1" tests bit one in the source register (R1). Because it is a "1", the relative address is added to the PC and the PC jumps to the memory location pointed to by the SKIP. (Remember that the memory location must be within the allowed range of + 127 to − 128.)

BXOR — Bit XOR

BXOR   dst,src.b

BXOR   dst.b,src

Operation: dst(0) ← dst(0) XOR src(b)

                or

dst(b) ← dst(b) XOR src(0)

The specified bit of the source (or the destination) is logically exclusive-ORed with bit zero (LSB) of the destination (or source). The result bit is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: **C:** Unaffected.
         Z: Set if the result is "0"; cleared otherwise.
         S: Cleared to "0".
         V: Undefined.
         D: Unaffected.
         H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc | dst | b | 0 | src	3	6	27	r0	Rb
opc | src | b | 1 | dst	3	6	27	Rb	r0

NOTE: In the second byte of the 3-byte instruction formats, the destination (or source) address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H (00000111B) and register 01H = 03H (00000011B):

BXOR   R1,01H.1   →   R1 = 06H, register 01H = 03H

BXOR   01H.2,R1   →   Register 01H = 07H, R1 = 07H

In the first example, destination working register R1 has the value 07H (00000111B) and source register 01H has the value 03H (00000011B). The statement "BXOR R1,01H.1" exclusive-ORs bit one of register 01H (source) with bit zero of R1 (destination). The result bit value is stored in bit zero of R1, changing its value from 07H to 06H. The value of source register 01H is unaffected.

CALL — Call Procedure

CALL   dst

Operation: SP   ←   SP − 1
                     @SP   ←   PCL
                     SP   ←   SP −1
                     @SP   ←   PCH
                     PC   ←   dst

The current contents of the program counter are pushed onto the top of the stack. The program counter value used is the address of the first instruction following the CALL instruction. The specified destination address is then loaded into the program counter and points to the first instruction of a procedure. At the end of the procedure the return instruction (RET) can be used to return to the original program flow. RET pops the top of the stack back into the program counter.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	3	14	F6	DA
opc	dst	2	12	F4	IRR
opc	dst	2	14	D4	IA

Example: Given: R0 = 35H, R1 = 21H, PC = 1A47H, and SP = 0002H:

CALL   3521H   →   SP = 0000H
                                   (Memory locations 0000H = 1AH, 0001H = 4AH, where 4AH is the address that follows the instruction.)

CALL   @RR0   →   SP = 0000H (0000H = 1AH, 0001H = 49H)

CALL   #40H   →   SP = 0000H (0000H = 1AH, 0001H = 49H)

In the first example, if the program counter value is 1A47H and the stack pointer contains the value 0002H, the statement "CALL 3521H" pushes the current PC value onto the top of the stack. The stack pointer now points to memory location 0000H. The PC is then loaded with the value 3521H, the address of the first instruction in the program sequence to be executed.

If the contents of the program counter and stack pointer are the same as in the first example, the statement "CALL @RR0" produces the same result except that the 49H is stored in stack location 0001H (because the two-byte instruction format was used). The PC is then loaded with the value 3521H, the address of the first instruction in the program sequence to be executed. Assuming that the contents of the program counter and stack pointer are the same as in the first example, if program address 0040H contains 35H and program address 0041H contains 21H, the statement "CALL #40H" produces the same result as in the second example.

SAMSUNG
ELECTRONICS

CCF — Complement Carry Flag

CCF

Operation:	C ← NOT C

The carry flag (C) is complemented. If C = "1", the value of the carry flag is changed to logic zero; if C = "0", the value of the carry flag is changed to logic one.

Flags: **C:** Complemented.

No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	EF

Example: Given: The carry flag = "0":

CCF

If the carry flag = "0", the CCF instruction complements it in the FLAGS register (0D5H), changing its value from logic zero to logic one.

CLR — Clear

CLR   dst

Operation: dst ← "0"

The destination location is cleared to "0".

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	4	B0	R
			4	B1	IR

Example: Given: Register 00H = 4FH, register 01H = 02H, and register 02H = 5EH:

CLR   00H   →   Register 00H = 00H

CLR   @01H   →   Register 01H = 02H, register 02H = 00H

In Register (R) addressing mode, the statement "CLR 00H" clears the destination register 00H value to 00H. In the second example, the statement "CLR @01H" uses Indirect Register (IR) addressing mode to clear the 02H register value to 00H.

SAMSUNG
ELECTRONICS

COM — Complement

COM   dst

Operation: dst ← NOT dst

The contents of the destination location are complemented (one's complement); all "1s" are changed to "0s", and vice-versa.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Always reset to "0".
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	4	60	R
			4	61	IR

Example: Given: R1 = 07H and register 07H = 0F1H:

COM   R1   →   R1 = 0F8H

COM   @R1   →   R1 = 07H, register 07H = 0EH

In the first example, destination working register R1 contains the value 07H (00000111B). The statement "COM R1" complements all the bits in R1: all logic ones are changed to logic zeros, and vice-versa, leaving the value 0F8H (11111000B).

In the second example, Indirect Register (IR) addressing mode is used to complement the value of destination register 07H (11110001B), leaving the new value 0EH (00001110B).

CP — Compare

CP   dst,src

Operation: dst – src

The source operand is compared to (subtracted from) the destination operand, and the appropriate flags are set accordingly. The contents of both operands are unaffected by the comparison.

Flags: **C:** Set if a "borrow" occurred (src > dst); cleared otherwise.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc | dst | src	2	4	A2	r	r
		6	A3	r	lr
opc | src | dst	3	6	A4	R	R
		6	A5	R	IR
opc | dst | src	3	6	A6	R	IM

Examples: 1. Given: R1 = 02H and R2 = 03H:

CP   R1,R2 →   Set the C and S flags

Destination working register R1 contains the value 02H and source register R2 contains the value 03H. The statement "CP R1,R2" subtracts the R2 value (source/subtrahend) from the R1 value (destination/minuend). Because a "borrow" occurs and the difference is negative, C and S are "1".

2. Given: R1 = 05H and R2 = 0AH:

```
        CP        R1,R2
        JP        UGE,SKIP
        INC       R1
SKIP    LD        R3,R1
```

In this example, destination working register R1 contains the value 05H which is less than the contents of the source working register R2 (0AH). The statement "CP R1,R2" generates C = "1" and the JP instruction does not jump to the SKIP location. After the statement "LD R3,R1" executes, the value 06H remains in working register R3.

SAMSUNG
ELECTRONICS

CPIJE — Compare, Increment, and Jump on Equal

CPIJE   dst,src,RA

Operation: If dst – src = "0", PC ← PC + RA

Ir ← Ir + 1

The source operand is compared to (subtracted from) the destination operand. If the result is "0", the relative address is added to the program counter and control passes to the statement whose address is now in the program counter. Otherwise, the instruction immediately following the CPIJE instruction is executed. In either case, the source pointer is incremented by one before the next instruction is executed.

Flags: No flags are affected.

Format:

				Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	RA	3	12	C2	r	Ir

NOTE: Execution time is 18 cycles if the jump is taken or 16 cycles if it is not taken.

Example: Given: R1 = 02H, R2 = 03H, and register 03H = 02H:

CPIJE   R1,@R2,SKIP   →   R2 = 04H, PC jumps to SKIP location

In this example, working register R1 contains the value 02H, working register R2 the value 03H, and register 03 contains 02H. The statement "CPIJE R1,@R2,SKIP" compares the @R2 value 02H (00000010B) to 02H (00000010B). Because the result of the comparison is *equal*, the relative address is added to the PC and the PC then jumps to the memory location pointed to by SKIP. The source register (R2) is incremented by one, leaving a value of 04H. (Remember that the memory location must be within the allowed range of + 127 to – 128.)

CPIJNE — Compare, Increment, and Jump on Non-Equal

CPIJNE   dst,src,RA

Operation: If dst – src _ "0", PC ← PC + RA

Ir ← Ir + 1

The source operand is compared to (subtracted from) the destination operand. If the result is not "0", the relative address is added to the program counter and control passes to the statement whose address is now in the program counter; otherwise the instruction following the CPIJNE instruction is executed. In either case the source pointer is incremented by one before the next instruction.

Flags: No flags are affected.

Format:

				Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	RA	3	12	D2	r	Ir

NOTE: Execution time is 18 cycles if the jump is taken or 16 cycles if it is not taken.

Example: Given: R1 = 02H, R2 = 03H, and register 03H = 04H:

CPIJNE   R1,@R2,SKIP   →   R2 = 04H, PC jumps to SKIP location

Working register R1 contains the value 02H, working register R2 (the source pointer) the value 03H, and general register 03 the value 04H. The statement "CPIJNE R1,@R2,SKIP" subtracts 04H (00000100B) from 02H (00000010B). Because the result of the comparison is *non-equal*, the relative address is added to the PC and the PC then jumps to the memory location pointed to by SKIP. The source pointer register (R2) is also incremented by one, leaving a value of 04H. (Remember that the memory location must be within the allowed range of + 127 to − 128.)

SAMSUNG
ELECTRONICS

DA — Decimal Adjust

DA dst

Operation: dst ← DA dst

The destination operand is adjusted to form two 4-bit BCD digits following an addition or subtraction operation. For addition (ADD, ADC) or subtraction (SUB, SBC), the following table indicates the operation performed. (The operation is undefined if the destination operand was not the result of a valid addition or subtraction of BCD digits):

Instruction	Carry Before DA	Bits 4–7 Value (Hex)	H Flag Before DA	Bits 0–3 Value (Hex)	Number Added to Byte	Carry After DA
	0	0–9	0	0–9	00	0
	0	0–8	0	A–F	06	0
	0	0–9	1	0–3	06	0
ADD	0	A–F	0	0–9	60	1
ADC	0	9–F	0	A–F	66	1
	0	A–F	1	0–3	66	1
	1	0–2	0	0–9	60	1
	1	0–2	0	A–F	66	1
	1	0–3	1	0–3	66	1
	0	0–9	0	0–9	00 = − 00	0
SUB	0	0–8	1	6–F	FA = − 06	0
SBC	1	7–F	0	0–9	A0 = − 60	1
	1	6–F	1	6–F	9A = − 66	1

Flags: **C:** Set if there was a carry from the most significant bit; cleared otherwise (see table).
Z: Set if result is "0"; cleared otherwise.
S: Set if result bit 7 is set; cleared otherwise.
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst		2	4	40	R
				4	41	IR

DA — Decimal Adjust

DA   (Continued)

Example: Given: Working register R0 contains the value 15 (BCD), working register R1 contains
                  27 (BCD), and address 27H contains 46 (BCD):

                  ADD   R1,R0   ;   C ← "0", H ← "0", Bits 4–7 = 3, bits 0–3 = C, R1 ← 3CH
                  DA   R1   ;   R1 ← 3CH + 06

                  If addition is performed using the BCD values 15 and 27, the result should be 42. The sum is
                  incorrect, however, when the binary representations are added in the destination location using
                  standard binary arithmetic:

                       0 0 0 1   0 1 0 1   15
                  +   0 0 1 0   0 1 1 1   27
                       0 0 1 1   1 1 0 0   =   3CH

                  The DA instruction adjusts this result so that the correct BCD representation is obtained:

                       0 0 1 1   1 1 0 0
                  +   0 0 0 0   0 1 1 0
                       0 1 0 0   0 0 1 0   =   42

                  Assuming the same values given above, the statements

                  SUB   27H,R0   ;   C ← "0", H ← "0", Bits 4–7 = 3, bits 0–3 = 1
                  DA   @R1   ;   @R1 ← 31–0

                  leave the value 31 (BCD) in address 27H (@R1).

DEC — Decrement

DEC   dst

Operation: dst ← dst – 1

The contents of the destination operand are decremented by one.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	4	00	R
			4	01	IR

Example: Given: R1 = 03H and register 03H = 10H:

DEC   R1   →   R1 = 02H

DEC   @R1   →   Register 03H = 0FH

In the first example, if working register R1 contains the value 03H, the statement "DEC R1" decrements the hexadecimal value by one, leaving the value 02H. In the second example, the statement "DEC @R1" decrements the value 10H contained in the destination register 03H by one, leaving the value 0FH.

DECW — Decrement Word

DECW   dst

Operation: dst ← dst – 1

The contents of the destination location (which must be an even address) and the operand following that location are treated as a single 16-bit value that is decremented by one.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	8	80	RR
			8	81	IR

Example: Given: R0 = 12H, R1 = 34H, R2 = 30H, register 30H = 0FH, and register 31H = 21H:

DECW   RR0   →   R0 = 12H, R1 = 33H

DECW   @R2   →   Register 30H = 0FH, register 31H = 20H

In the first example, destination register R0 contains the value 12H and register R1 the value 34H. The statement "DECW RR0" addresses R0 and the following operand R1 as a 16-bit word and decrements the value of R1 by one, leaving the value 33H.

NOTE: A system malfunction may occur if you use a Zero flag (FLAGS.6) result together with a DECW instruction. To avoid this problem, we recommend that you use DECW as shown in the following example:

```
LOOP:    DECW    RR0
         LD      R2,R1
         OR      R2,R0
         JR      NZ,LOOP
```

SAMSUNG
ELECTRONICS

DI — Disable Interrupts

DI

Operation: SYM (0) ← 0

Bit zero of the system mode control register, SYM.0, is cleared to "0", globally disabling all interrupt processing. Interrupt requests will continue to set their respective interrupt pending bits, but the CPU will not service them while interrupt processing is disabled.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	8F

Example: Given: SYM = 01H:

DI

If the value of the SYM register is 01H, the statement "DI" leaves the new value 00H in the register and clears SYM.0 to "0", disabling interrupt processing.

Before changing IMR, interrupt pending and interrupt source control register, be sure DI state.

DIV — Divide (Unsigned)

DIV   dst,src

Operation: dst ÷ src

dst (UPPER) ← REMAINDER

dst (LOWER) ← QUOTIENT

The destination operand (16 bits) is divided by the source operand (8 bits). The quotient (8 bits) is stored in the lower half of the destination. The remainder (8 bits) is stored in the upper half of the destination. When the quotient is $\geq 2^8$, the numbers stored in the upper and lower halves of the destination for quotient and remainder are incorrect. Both operands are treated as unsigned integers.

Flags: **C:** Set if the V flag is set and quotient is between 2^8 and $2^9 - 1$; cleared otherwise.
Z: Set if divisor or quotient = "0"; cleared otherwise.
S: Set if MSB of quotient = "1"; cleared otherwise.
V: Set if quotient is $\geq 2^8$ or if divisor = "0"; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	3	26/10	94	RR	R
				26/10	95	RR	IR
				26/10	96	RR	IM

NOTE: Execution takes 10 cycles if the divide-by-zero is attempted; otherwise it takes 26 cycles.

Examples: Given: R0 = 10H, R1 = 03H, R2 = 40H, register 40H = 80H:

DIV   RR0,R2   →   R0 = 03H, R1 = 40H

DIV   RR0,@R2   →   R0 = 03H, R1 = 20H

DIV   RR0,#20H   →   R0 = 03H, R1 = 80H

In the first example, destination working register pair RR0 contains the values 10H (R0) and 03H (R1), and register R2 contains the value 40H. The statement "DIV RR0,R2" divides the 16-bit RR0 value by the 8-bit value of the R2 (source) register. After the DIV instruction, R0 contains the value 03H and R1 contains 40H. The 8-bit remainder is stored in the upper half of the destination register RR0 (R0) and the quotient in the lower half (R1).

SAMSUNG
ELECTRONICS

DJNZ — Decrement and Jump if Non-Zero

DJNZ   r,dst

Operation: $r \leftarrow r - 1$

If r _ 0, PC $\leftarrow$ PC + dst

The working register being used as a counter is decremented. If the contents of the register are not logic zero after decrementing, the relative address is added to the program counter and control passes to the statement whose address is now in the PC. The range of the relative address is +127 to −128, and the original value of the PC is taken to be the address of the instruction byte following the DJNZ statement.

NOTE: In case of using DJNZ instruction, the working register being used as a counter should be set at the one of location 0C0H to 0CFH with SRP, SRP0, or SRP1 instruction.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
r | opc	dst	2	8 (jump taken)	rA	RA
			8 (no jump)	r = 0 to F	

Example: Given: R1 = 02H and LOOP is the label of a relative address:

SRP   #0C0H
DJNZ   R1,LOOP

DJNZ is typically used to control a "loop" of instructions. In many cases, a label is used as the destination operand instead of a numeric relative address value. In the example, working register R1 contains the value 02H, and LOOP is the label for a relative address.

The statement "DJNZ R1, LOOP" decrements register R1 by one, leaving the value 01H. Because the contents of R1 after the decrement are non-zero, the jump is taken to the relative address specified by the LOOP label.

EI — Enable Interrupts

EI

Operation: SYM (0) ← 1

An EI instruction sets bit zero of the system mode register, SYM.0 to "1". This allows interrupts to be serviced as they occur (assuming they have highest priority). If an interrupt's pending bit was set while interrupt processing was disabled (by executing a DI instruction), it will be serviced when you execute the EI instruction.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	9F

Example: Given: SYM = 00H:

EI

If the SYM register contains the value 00H, that is, if interrupts are currently disabled, the statement "EI" sets the SYM register to 01H, enabling all interrupts. (SYM.0 is the enable bit for global interrupt processing.)

SAMSUNG
ELECTRONICS

ENTER — Enter

ENTER

Operation: SP   ←   SP – 2
                  @SP   ←   IP
                  IP   ←   PC
                  PC   ←   @IP
                  IP   ←   IP + 2

This instruction is useful when implementing threaded-code languages. The contents of the instruction pointer are pushed to the stack. The program counter (PC) value is then written to the instruction pointer. The program memory word that is pointed to by the instruction pointer is loaded into the PC, and the instruction pointer is incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	14	1F

Example: The diagram below shows one example of how to use an ENTER statement.
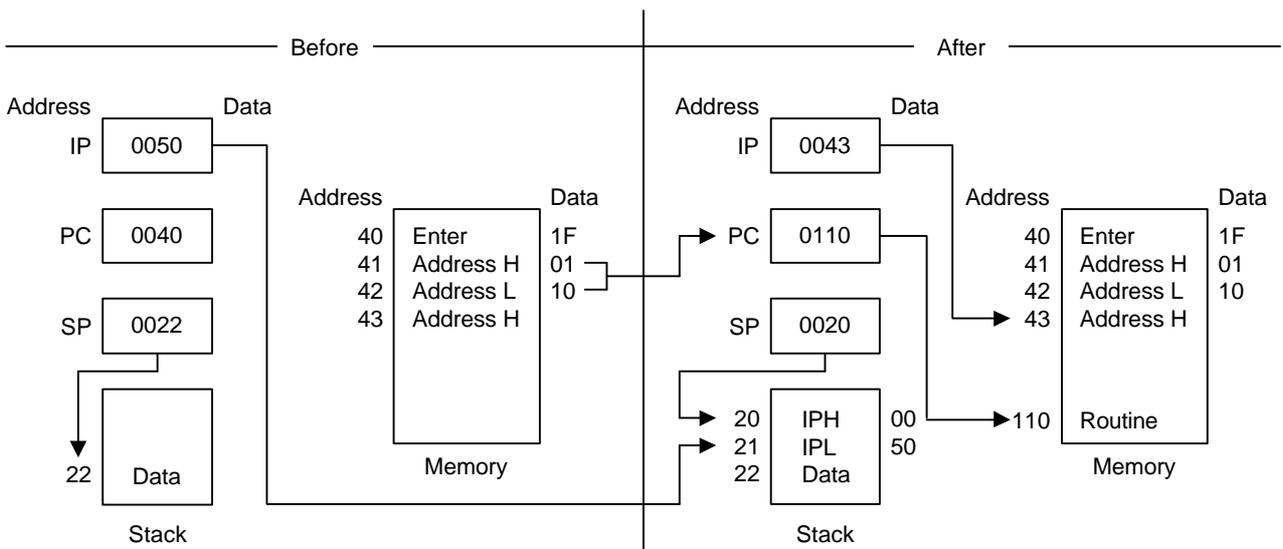

EXIT — Exit

EXIT

Operation: IP   ←   @SP
               SP   ←   SP + 2
               PC   ←   @IP
               IP   ←   IP + 2

This instruction is useful when implementing threaded-code languages. The stack value is popped and loaded into the instruction pointer. The program memory word that is pointed to by the instruction pointer is then loaded into the program counter, and the instruction pointer is incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	14 (internal stack)	2F
		16 (internal stack)	

Example: The diagram below shows one example of how to use an EXIT statement.
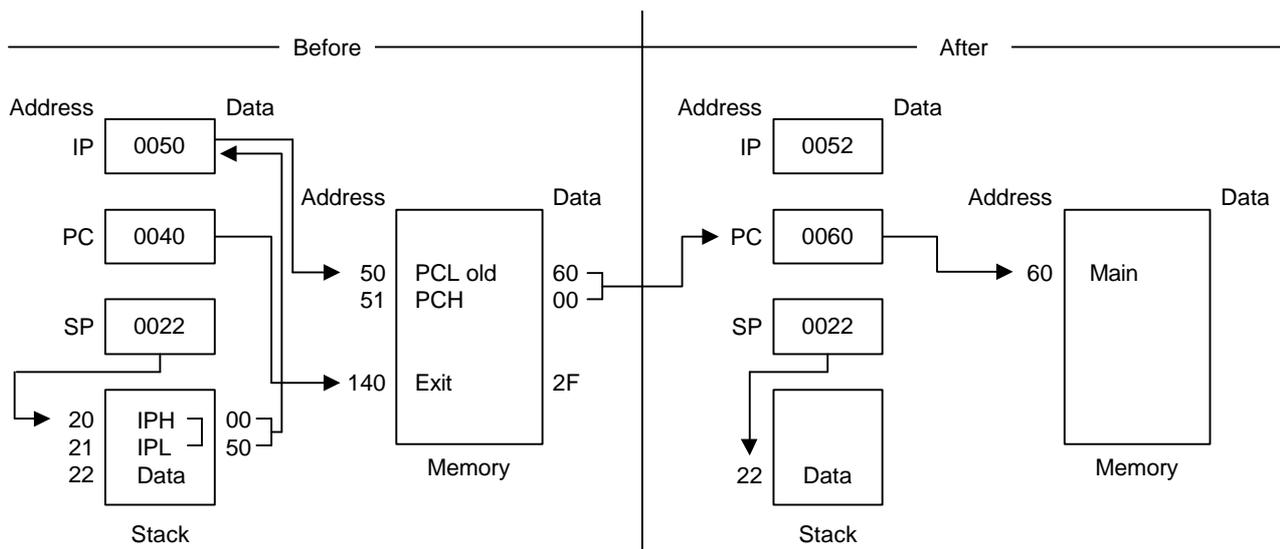

IDLE — Idle Operation

IDLE

Operation:

The IDLE instruction stops the CPU clock while allowing system clock oscillation to continue. Idle mode can be released by an interrupt request (IRQ) or an external reset operation.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	1	4	6F	–	–

Example: The instruction

IDLE
NOP
NOP
NOP

stops the CPU clock but not the system clock.

INC — Increment

INC   dst

Operation: dst ← dst + 1

The contents of the destination operand are incremented by one.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
dst | opc	1	4	rE	r
			r = 0 to F	
opc dst	2	4	20	R
		4	21	IR

Example: Given: R0 = 1BH, register 00H = 0CH, and register 1BH = 0FH:

INC   R0   →   R0 = 1CH
INC   00H   →   Register 00H = 0DH
INC   @R0   →   R0 = 1BH, register 01H = 10H

In the first example, if destination working register R0 contains the value 1BH, the statement "INC R0" leaves the value 1CH in that same register.

The next example shows the effect an INC instruction has on register 00H, assuming that it contains the value 0CH.

In the third example, INC is used in Indirect Register (IR) addressing mode to increment the value of register 1BH from 0FH to 10H.

INCW — Increment Word

INCW   dst

Operation: dst ← dst + 1

The contents of the destination (which must be an even address) and the byte following that location are treated as a single 16-bit value that is incremented by one.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	8	A0	RR
			8	A1	IR

Example: Given: R0 = 1AH, R1 = 02H, register 02H = 0FH, and register 03H = 0FFH:

INCW   RR0   →   R0 = 1AH, R1 = 03H

INCW   @R1   →   Register 02H = 10H, register 03H = 00H

In the first example, the working register pair RR0 contains the value 1AH in register R0 and 02H in register R1. The statement "INCW RR0" increments the 16-bit destination by one, leaving the value 03H in register R1. In the second example, the statement "INCW @R1" uses Indirect Register (IR) addressing mode to increment the contents of general register 03H from 0FFH to 00H and register 02H from 0FH to 10H.

NOTE: A system malfunction may occur if you use a Zero (Z) flag (FLAGS.6) result together with an INCW instruction. To avoid this problem, we recommend that you use INCW as shown in the following example:

```
LOOP:    INCW      RR0
         LD        R2,R1
         OR        R2,R0
         JR        NZ,LOOP
```

IRET — Interrupt Return

IRET IRET (Normal) IRET (Fast)

Operation: FLAGS ← @SP   PC ↔ IP
SP ← SP + 1   FLAGS ← FLAGS'
PC ← @SP   FIS ← 0
SP ← SP + 2
SYM(0) ← 1

This instruction is used at the end of an interrupt service routine. It restores the flag register and the program counter. It also re-enables global interrupts. A "normal IRET" is executed only if the fast interrupt status bit (FIS, bit one of the FLAGS register, 0D5H) is cleared (= "0"). If a fast interrupt occurred, IRET clears the FIS bit that was set at the beginning of the service routine.

Flags: All flags are restored to their original settings (that is, the settings before the interrupt occurred).

Format:

IRET (Normal)	**Bytes**	**Cycles**	**Opcode (Hex)**
opc	1	10 (internal stack) 12 (external stack)	BF

IRET (Fast)	**Bytes**	**Cycles**	**Opcode (Hex)**
opc	1	6	BF

Example: In the figure below, the instruction pointer is initially loaded with 100H in the main program before interrupts are enabled. When an interrupt occurs, the program counter and instruction pointer are swapped. This causes the PC to jump to address 100H and the IP to keep the return address. The last instruction in the service routine normally is a jump to IRET at address FFH. This causes the instruction pointer to be loaded with 100H "again" and the program counter to jump back to the main program. Now, the next interrupt can occur and the IP is still correct at 100H.

```
        0H   ┌──────────┐
       FFH   │ IRET     │
      100H   ├──────────┤
             │ Interrupt│
             │ Service  │
             │ Routine  │
             ├──────────┤
             │ JP to FFH│
     FFFFH   └──────────┘
```
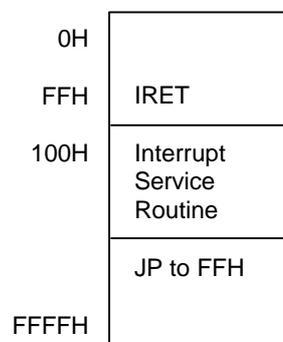

NOTE: In the fast interrupt example above, if the last instruction is not a jump to IRET, you must pay attention to the order of the last two instructions. The IRET cannot be immediately proceeded by a clearing of the interrupt status (as with a reset of the IPR register).

SAMSUNG
ELECTRONICS

JP — Jump

JP   cc,dst   (Conditional)

JP   dst   (Unconditional)

Operation: If cc is true, PC ← dst

The conditional JUMP instruction transfers program control to the destination address if the condition specified by the condition code (cc) is true; otherwise, the instruction following the JP instruction is executed. The unconditional JP simply replaces the contents of the PC with the contents of the specified register pair. Control then passes to the statement addressed by the PC.

Flags: No flags are affected.

Format: [1]

		Bytes	Cycles	Opcode (Hex)	Addr Mode <ins>dst</ins>
cc | opc	dst	3	8	ccD	DA
(2)				cc = 0 to F	
opc	dst	2	8	30	IRR

NOTES:
1. The 3-byte format is used for a conditional jump and the 2-byte format for an unconditional jump.
2. In the first byte of the three-byte instruction format (conditional jump), the condition code and the opcode are both four bits.

Example: Given: The carry flag (C) = "1", register 00 = 01H, and register 01 = 20H:

JP   C,LABEL_W   →   LABEL_W = 1000H, PC = 1000H

JP   @00H   →   PC = 0120H

The first example shows a conditional JP. Assuming that the carry flag is set to "1", the statement
"JP C,LABEL_W" replaces the contents of the PC with the value 1000H and transfers control to that location. Had the carry flag not been set, control would then have passed to the statement immediately following the JP instruction.

The second example shows an unconditional JP. The statement "JP @00" replaces the contents of the PC with the contents of the register pair 00H and 01H, leaving the value 0120H.

JR — Jump Relative

JR   cc,dst

Operation: If cc is true, PC ← PC + dst

If the condition specified by the condition code (cc) is true, the relative address is added to the program counter and control passes to the statement whose address is now in the program counter; otherwise, the instruction following the JR instruction is executed. (See list of condition codes).

The range of the relative address is +127, −128, and the original value of the program counter is taken to be the address of the first instruction byte following the JR statement.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
(1) cc | opc dst	2	6	ccB	RA
			cc = 0 to F	

NOTE: In the first byte of the two-byte instruction format, the condition code and the opcode are each four bits.

Example: Given: The carry flag = "1" and LABEL_X = 1FF7H:

JR   C,LABEL_X   →   PC = 1FF7H

If the carry flag is set (that is, if the condition code is true), the statement "JR C,LABEL_X" will pass control to the statement whose address is now in the PC. Otherwise, the program instruction following the JR would be executed.

SAMSUNG
ELECTRONICS

LD — Load

LD   dst,src

Operation: dst ← src

The contents of the source are loaded into the destination. The source's contents are unaffected.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
dst | opc src	2	4	rC	r	IM
		4	r8	r	R
src | opc dst	2	4	r9	R	r
		r = 0 to F			
opc dst | src	2	4	C7	r	Ir
		4	D7	Ir	r
opc src dst	3	6	E4	R	R
		6	E5	R	IR
opc dst src	3	6	E6	R	IM
		6	D6	IR	IM
opc src dst	3	6	F5	IR	R
opc dst | src x	3	6	87	r	x [r]
opc src | dst x	3	6	97	x [r]	r

LD — Load

LD   (Continued)

Examples: Given: R0 = 01H, R1 = 0AH, register 00H = 01H, register 01H = 20H,
                   register 02H = 02H, LOOP = 30H, and register 3AH = 0FFH:

LD	R0,#10H	→	R0 = 10H
LD	R0,01H	→	R0 = 20H, register 01H = 20H
LD	01H,R0	→	Register 01H = 01H, R0 = 01H
LD	R1,@R0	→	R1 = 20H, R0 = 01H
LD	@R0,R1	→	R0 = 01H, R1 = 0AH, register 01H = 0AH
LD	00H,01H	→	Register 00H = 20H, register 01H = 20H
LD	02H,@00H	→	Register 02H = 20H, register 00H = 01H
LD	00H,#0AH	→	Register 00H = 0AH
LD	@00H,#10H	→	Register 00H = 01H, register 01H = 10H
LD	@00H,02H	→	Register 00H = 01H, register 01H = 02, register 02H = 02H
LD	R0,#LOOP[R1]	→	R0 = 0FFH, R1 = 0AH
LD	#LOOP[R0],R1	→	Register 31H = 0AH, R0 = 01H, R1 = 0AH

LDB — Load Bit

LDB   dst,src.b

LDB   dst.b,src

Operation: dst(0) ← src(b)

                    or

dst(b) ← src(0)

The specified bit of the source is loaded into bit zero (LSB) of the destination, or bit zero of the source is loaded into the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | b | 0	src	3	6	47	r0	Rb
opc	src | b | 1	dst	3	6	47	Rb	r0

NOTE: In the second byte of the instruction formats, the destination (or source) address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Examples: Given: R0 = 06H and general register 00H = 05H:

LDB   R0,00H.2   →   R0 = 07H, register 00H = 05H

LDB   00H.0,R0   →   R0 = 06H, register 00H = 04H

In the first example, destination working register R0 contains the value 06H and the source general register 00H the value 05H. The statement "LD R0,00H.2" loads the bit two value of the 00H register into bit zero of the R0 register, leaving the value 07H in register R0.

In the second example, 00H is the destination register. The statement "LD 00H.0,R0" loads bit zero of register R0 to the specified bit (bit zero) of the destination register, leaving 04H in general register 00H.

LDC/LDE — **Load Memory**

LDC/LDE   dst,src

Operation: dst ← src

This instruction loads a byte from program or data memory into a working register or vice-versa. The source values are unaffected. LDC refers to program memory and LDE to data memory. The assembler makes 'Irr' or 'rr' values an even number for program memory and odd an odd number for data memory.

Flags: No flags are affected.

Format:

					Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
1.	opc	dst | src			2	10	C3	r	Irr
2.	opc	src | dst			2	10	D3	Irr	r
3.	opc	dst | src	XS		3	12	E7	r	XS [rr]
4.	opc	src | dst	XS		3	12	F7	XS [rr]	r
5.	opc	dst | src	XL$_L$	XL$_H$	4	14	A7	r	XL [rr]
6.	opc	src | dst	XL$_L$	XL$_H$	4	14	B7	XL [rr]	r
7.	opc	dst | 0000	DA$_L$	DA$_H$	4	14	A7	r	DA
8.	opc	src | 0000	DA$_L$	DA$_H$	4	14	B7	DA	r
9.	opc	dst | 0001	DA$_L$	DA$_H$	4	14	A7	r	DA
10.	opc	src | 0001	DA$_L$	DA$_H$	4	14	B7	DA	r

NOTES:
1. The source (src) or working register pair [rr] for formats 5 and 6 cannot use register pair 0–1.
2. For formats 3 and 4, the destination address 'XS [rr]' and the source address 'XS [rr]' are each one byte.
3. For formats 5 and 6, the destination address 'XL [rr] and the source address 'XL [rr]' are each two bytes.
4. The DA and r source values for formats 7 and 8 are used to address program memory; the second set of values, used in formats 9 and 10, are used to address data memory.

SAMSUNG
ELECTRONICS

LDC/LDE — Load Memory

LDC/LDE   (Continued)

Examples: Given: R0 = 11H, R1 = 34H, R2 = 01H, R3 = 04H; Program memory locations
0103H = 4FH, 0104H = 1A, 0105H = 6DH, and 1104H = 88H. External data memory
locations 0103H = 5FH, 0104H = 2AH, 0105H = 7DH, and 1104H = 98H:

LDC	R0,@RR2	; R0 ← contents of program memory location 0104H ; R0 = 1AH, R2 = 01H, R3 = 04H
LDE	R0,@RR2	; R0 ← contents of external data memory location 0104H ; R0 = 2AH, R2 = 01H, R3 = 04H
LDC [note]	@RR2,R0	; 11H (contents of R0) is loaded into program memory ; location 0104H (RR2), ; working registers R0, R2, R3 → no change
LDE	@RR2,R0	; 11H (contents of R0) is loaded into external data memory ; location 0104H (RR2), ; working registers R0, R2, R3 → no change
LDC	R0,#01H[RR2]	; R0 ← contents of program memory location 0105H ; (01H + RR2), ; R0 = 6DH, R2 = 01H, R3 = 04H
LDE	R0,#01H[RR2]	; R0 ← contents of external data memory location 0105H ; (01H + RR2), R0 = 7DH, R2 = 01H, R3 = 04H
LDC [note]	#01H[RR2],R0	; 11H (contents of R0) is loaded into program memory location ; 0105H (01H + 0104H)
LDE	#01H[RR2],R0	; 11H (contents of R0) is loaded into external data memory ; location 0105H (01H + 0104H)
LDC	R0,#1000H[RR2]	; R0 ← contents of program memory location 1104H ; (1000H + 0104H), R0 = 88H, R2 = 01H, R3 = 04H
LDE	R0,#1000H[RR2]	; R0 ← contents of external data memory location 1104H ; (1000H + 0104H), R0 = 98H, R2 = 01H, R3 = 04H
LDC	R0,1104H	; R0 ← contents of program memory location 1104H, R0 = 88H
LDE	R0,1104H	; R0 ← contents of external data memory location 1104H, ; R0 = 98H
LDC [note]	1105H,R0	; 11H (contents of R0) is loaded into program memory location ; 1105H, (1105H) ← 11H
LDE	1105H,R0	; 11H (contents of R0) is loaded into external data memory ; location 1105H, (1105H) ← 11H

NOTE: These instructions are not supported by masked ROM type devices.

LDCD/LDED — Load Memory and Decrement

LDCD/LDED   dst,src

Operation: dst ← src

rr ← rr − 1

These instructions are used for user stacks or block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair. The contents of the source location are loaded into the destination location. The memory address is then decremented. The contents of the source are unaffected.

LDCD references program memory and LDED references external data memory. The assembler makes 'Irr' an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src	2	10	E2	r	Irr

Examples: Given: R6 = 10H, R7 = 33H, R8 = 12H, program memory location 1033H = 0CDH, and external data memory location 1033H = 0DDH:

LDCD   R8,@RR6   ; 0CDH (contents of program memory location 1033H) is loaded
                         ; into R8 and RR6 is decremented by one
                         ; R8 = 0CDH, R6 = 10H, R7 = 32H (RR6 ← RR6 − 1)

LDED   R8,@RR6   ; 0DDH (contents of data memory location 1033H) is loaded
                         ; into R8 and RR6 is decremented by one (RR6 ← RR6 − 1)
                         ; R8 = 0DDH, R6 = 10H, R7 = 32H

SAMSUNG
ELECTRONICS

LDCI/LDEI — Load Memory and Increment

LDCI/LDEI   dst,src

Operation: dst ← src

rr ← rr + 1

These instructions are used for user stacks or block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair. The contents of the source location are loaded into the destination location. The memory address is then incremented automatically. The contents of the source are unaffected.

LDCI refers to program memory and LDEI refers to external data memory. The assembler makes 'Irr' even for program memory and odd for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src	2	10	E3	r	Irr

Examples: Given: R6 = 10H, R7 = 33H, R8 = 12H, program memory locations 1033H = 0CDH and 1034H = 0C5H; external data memory locations 1033H = 0DDH and 1034H = 0D5:

LDCI   R8,@RR6   ;   0CDH (contents of program memory location 1033H) is loaded
                         ;   into R8 and RR6 is incremented by one (RR6 ← RR6 + 1)
                         ;   R8 = 0CDH, R6 = 10H, R7 = 34H

LDEI   R8,@RR6   ;   0DDH (contents of data memory location 1033H) is loaded
                         ;   into R8 and RR6 is incremented by one (RR6 ← RR6 + 1)
                         ;   R8 = 0DDH, R6 = 10H, R7 = 34H

LDCPD/LDEPD — Load Memory with Pre-Decrement

LDCPD/

LDEPD   dst,src

Operation: rr ← rr − 1

dst ← src

These instructions are used for block transfers of data from program or data memory from the register file. The address of the memory location is specified by a working register pair and is first decremented. The contents of the source location are then loaded into the destination location. The contents of the source are unaffected.

LDCPD refers to program memory and LDEPD refers to external data memory. The assembler makes 'Irr' an even number for program memory and an odd number for external data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src | dst	2	14	F2	Irr	r

Examples: Given: R0 = 77H, R6 = 30H, and R7 = 00H:

LDCPD   @RR6,R0   ; (RR6 ← RR6 − 1)
                         ; 77H (contents of R0) is loaded into program memory location
                         ; 2FFFH (3000H − 1H)
                         ; R0 = 77H, R6 = 2FH, R7 = 0FFH

LDEPD   @RR6,R0   ; (RR6 ← RR6 − 1)
                         ; 77H (contents of R0) is loaded into external data memory
                         ; location 2FFFH (3000H − 1H)
                         ; R0 = 77H, R6 = 2FH, R7 = 0FFH

SAMSUNG
ELECTRONICS

LDCPI/LDEPI — Load Memory with Pre-Increment

LDCPI/

LDEPI   dst,src

Operation: rr ← rr + 1

                 dst ← src

These instructions are used for block transfers of data from program or data memory from the register file. The address of the memory location is specified by a working register pair and is first incremented. The contents of the source location are loaded into the destination location. The contents of the source are unaffected.

LDCPI refers to program memory and LDEPI refers to external data memory. The assembler makes 'Irr' an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src | dst	2	14	F3	Irr	r

Examples: Given: R0 = 7FH, R6 = 21H, and R7 = 0FFH:

LDCPI   @RR6,R0   ; (RR6 ← RR6 + 1)
                        ; 7FH (contents of R0) is loaded into program memory
                        ; location 2200H (21FFH + 1H)
                        ; R0 = 7FH, R6 = 22H, R7 = 00H

LDEPI   @RR6,R0   ; (RR6 ← RR6 + 1)
                        ; 7FH (contents of R0) is loaded into external data memory
                        ; location 2200H (21FFH + 1H)
                        ; R0 = 7FH, R6 = 22H, R7 = 00H

LDW — Load Word

LDW dst,src

Operation: dst ← src

The contents of the source (a word) are loaded into the destination. The contents of the source are unaffected.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	3	8	C4	RR	RR
				8	C5	RR	IR
opc	dst	src	4	8	C6	RR	IML

Examples: Given: R4 = 06H, R5 = 1CH, R6 = 05H, R7 = 02H, register 00H = 1AH, register 01H = 02H, register 02H = 03H, and register 03H = 0FH:

LDW	RR6,RR4	→	R6 = 06H, R7 = 1CH, R4 = 06H, R5 = 1CH
LDW	00H,02H	→	Register 00H = 03H, register 01H = 0FH, register 02H = 03H, register 03H = 0FH
LDW	RR2,@R7	→	R2 = 03H, R3 = 0FH,
LDW	04H,@01H	→	Register 04H = 03H, register 05H = 0FH
LDW	RR6,#1234H	→	R6 = 12H, R7 = 34H
LDW	02H,#0FEDH	→	Register 02H = 0FH, register 03H = 0EDH

In the second example, please note that the statement "LDW 00H,02H" loads the contents of the source word 02H, 03H into the destination word 00H, 01H. This leaves the value 03H in general register 00H and the value 0FH in register 01H.

The other examples show how to use the LDW instruction with various addressing modes and formats.

SAMSUNG
ELECTRONICS

MULT — Multiply (Unsigned)

MULT   dst,src

Operation: dst ← dst × src

The 8-bit destination operand (even register of the register pair) is multiplied by the source operand (8 bits) and the product (16 bits) is stored in the register pair specified by the destination address. Both operands are treated as unsigned integers.

Flags: **C:** Set if result is > 255; cleared otherwise.
            Z: Set if the result is "0"; cleared otherwise.
            S: Set if MSB of the result is a "1"; cleared otherwise.
            V: Cleared.
            D: Unaffected.
            H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	3	22	84	RR	R
				22	85	RR	IR
				22	86	RR	IM

Examples: Given: Register 00H = 20H, register 01H = 03H, register 02H = 09H, register 03H = 06H:

MULT   00H, 02H   →   Register 00H = 01H, register 01H = 20H, register 02H = 09H
MULT   00H, @01H   →   Register 00H = 00H, register 01H = 0C0H
MULT   00H, #30H   →   Register 00H = 06H, register 01H = 00H

In the first example, the statement "MULT 00H,02H" multiplies the 8-bit destination operand (in the register 00H of the register pair 00H, 01H) by the source register 02H operand (09H). The 16-bit product, 0120H, is stored in the register pair 00H, 01H.

NEXT — Next

NEXT

Operation: PC ← @ IP

IP ← IP + 2

The NEXT instruction is useful when implementing threaded-code languages. The program memory word that is pointed to by the instruction pointer is loaded into the program counter. The instruction pointer is then incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	10	0F

Example: The following diagram shows one example of how to use the NEXT instruction.

SAMSUNG
ELECTRONICS
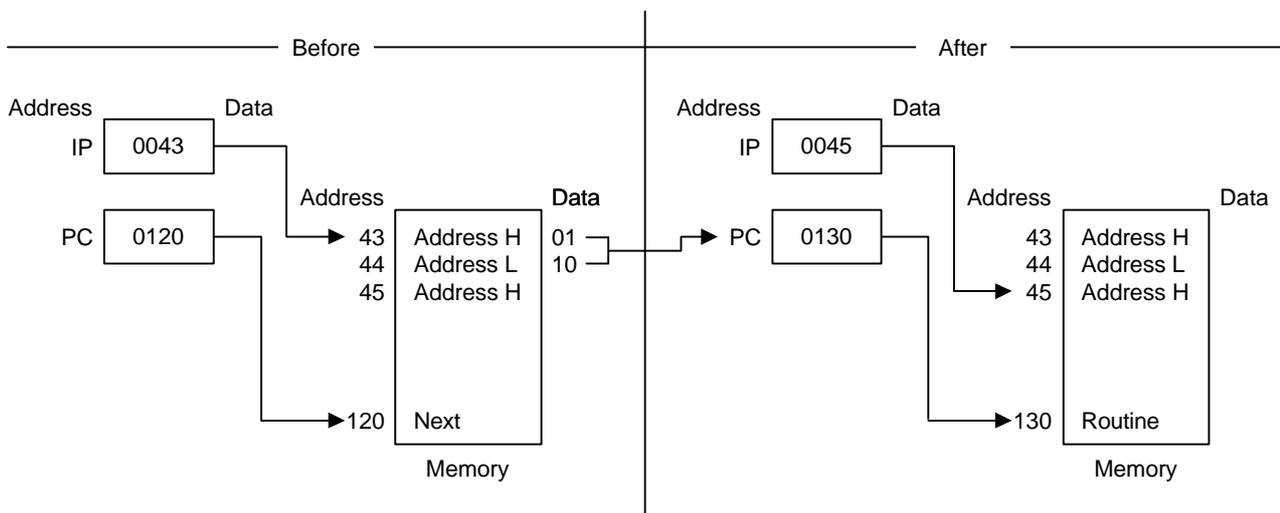

NOP — No Operation

NOP

Operation: No action is performed when the CPU executes this instruction. Typically, one or more NOPs are executed in sequence in order to effect a timing delay of variable duration.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	FF

Example: When the instruction

NOP

is encountered in a program, no operation occurs. Instead, there is a delay in instruction execution time.

OR — Logical OR

OR   dst,src

Operation: dst ← dst OR src

The source operand is logically ORed with the destination operand and the result is stored in the destination. The contents of the source are unaffected. The OR operation results in a "1" being stored whenever either of the corresponding bits in the two operands is a "1"; otherwise a "0" is stored.

Flags: **C:** Unaffected.
             Z: Set if the result is "0"; cleared otherwise.
             S: Set if the result bit 7 is set; cleared otherwise.
             V: Always cleared to "0".
             D: Unaffected.
             H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src	2	4	42	r	r
			6	43	r	lr
opc	src	dst	3	6	44	R	R
			6	45	R	IR
opc	dst	src	3	6	46	R	IM

Examples: Given: R0 = 15H, R1 = 2AH, R2 = 01H, register 00H = 08H, register 01H = 37H, and register 08H = 8AH:

OR   R0,R1   →   R0 = 3FH, R1 = 2AH

OR   R0,@R2   →   R0 = 37H, R2 = 01H, register 01H = 37H

OR   00H,01H   →   Register 00H = 3FH, register 01H = 37H

OR   01H,@00H   →   Register 00H = 08H, register 01H = 0BFH

OR   00H,#02H   →   Register 00H = 0AH

In the first example, if working register R0 contains the value 15H and register R1 the value 2AH, the statement "OR R0,R1" logical-ORs the R0 and R1 register contents and stores the result (3FH) in destination register R0.

The other examples show the use of the logical OR instruction with the various addressing modes and formats.

POP — Pop From Stack

POP   dst

Operation: dst ← @SP

SP ← SP + 1

The contents of the location addressed by the stack pointer are loaded into the destination. The stack pointer is then incremented by one.

Flags: No flags affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	8	50	R
			8	51	IR

Examples: Given: Register 00H = 01H, register 01H = 1BH, SPH (0D8H) = 00H, SPL (0D9H) = 0FBH, and stack register 0FBH = 55H:

POP   00H   →   Register 00H = 55H, SP = 00FCH

POP   @00H   →   Register 00H = 01H, register 01H = 55H, SP = 00FCH

In the first example, general register 00H contains the value 01H. The statement "POP 00H" loads the contents of location 00FBH (55H) into destination register 00H and then increments the stack pointer by one. Register 00H then contains the value 55H and the SP points to location 00FCH.

POPUD — **Pop User Stack (Decrementing)**

POPUD   dst,src

Operation: dst ← src

IR ← IR − 1

This instruction is used for user-defined stacks in the register file. The contents of the register file location addressed by the user stack pointer are loaded into the destination. The user stack pointer is then decremented.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	3	8	92	R	IR

Example: Given: Register 00H = 42H (user stack pointer register), register 42H = 6FH, and register 02H = 70H:

POPUD   02H,@00H   →   Register 00H = 41H, register 02H = 6FH, register 42H = 6FH

If general register 00H contains the value 42H and register 42H the value 6FH, the statement "POPUD 02H,@00H" loads the contents of register 42H into the destination register 02H. The user stack pointer is then decremented by one, leaving the value 41H.

SAMSUNG
ELECTRONICS

POPUI — Pop User Stack (Incrementing)

POPUI   dst,src

Operation: dst ← src

IR ← IR + 1

The POPUI instruction is used for user-defined stacks in the register file. The contents of the register file location addressed by the user stack pointer are loaded into the destination. The user stack pointer is then incremented.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	3	8	93	R	IR

Example: Given: Register 00H = 01H and register 01H = 70H:

POPUI   02H,@00H   →   Register 00H = 02H, register 01H = 70H, register 02H = 70H

If general register 00H contains the value 01H and register 01H the value 70H, the statement "POPUI 02H,@00H" loads the value 70H into the destination general register 02H. The user stack pointer (register 00H) is then incremented by one, changing its value from 01H to 02H.

PUSH — **Push To Stack**

PUSH   src

Operation: SP ← SP − 1

@SP ← src

A PUSH instruction decrements the stack pointer value and loads the contents of the source (src) into the location addressed by the decremented stack pointer. The operation then adds the new value to the top of the stack.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	src	2	8 (internal clock) 8 (external clock)	70	R
			8 (internal clock) 8 (external clock)	71	IR

Examples: Given: Register 40H = 4FH, register 4FH = 0AAH, SPH = 00H, and SPL = 00H:

PUSH   40H   →   Register 40H = 4FH, stack register 0FFH = 4FH,
                                  SPH = 0FFH, SPL = 0FFH

PUSH   @40H   →   Register 40H = 4FH, register 4FH = 0AAH, stack register
                                  0FFH = 0AAH, SPH = 0FFH, SPL = 0FFH

In the first example, if the stack pointer contains the value 0000H, and general register 40H the value 4FH, the statement "PUSH 40H" decrements the stack pointer from 0000 to 0FFFFH. It then loads the contents of register 40H into location 0FFFFH and adds this new value to the top of the stack.

PUSHUD — Push User Stack (Decrementing)

PUSHUD   dst,src

Operation: IR ← IR − 1

dst ← src

This instruction is used to address user-defined stacks in the register file. PUSHUD decrements the user stack pointer and loads the contents of the source into the register addressed by the decremented stack pointer.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst	src	3	8	82	IR	R

Example: Given: Register 00H = 03H, register 01H = 05H, and register 02H = 1AH:

PUSHUD @00H,01H →   Register 00H = 02H, register 01H = 05H, register 02H = 05H

If the user stack pointer (register 00H, for example) contains the value 03H, the statement "PUSHUD @00H,01H" decrements the user stack pointer by one, leaving the value 02H. The 01H register value, 05H, is then loaded into the register addressed by the decremented user stack pointer.

PUSHUI — **Push User Stack (Incrementing)**

PUSHUI dst,src

Operation: IR ← IR + 1

dst ← src

This instruction is used for user-defined stacks in the register file. PUSHUI increments the user stack pointer and then loads the contents of the source into the register location addressed by the incremented user stack pointer.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst	src	3	8	83	IR	R

Example: Given: Register 00H = 03H, register 01H = 05H, and register 04H = 2AH:

PUSHUI @00H,01H → Register 00H = 04H, register 01H = 05H, register 04H = 05H

If the user stack pointer (register 00H, for example) contains the value 03H, the statement "PUSHUI @00H,01H" increments the user stack pointer by one, leaving the value 04H. The 01H register value, 05H, is then loaded into the location addressed by the incremented user stack pointer.

SAMSUNG
ELECTRONICS

RCF — Reset Carry Flag

RCF　　　　　RCF

Operation:　　C ← 0

The carry flag is cleared to logic zero, regardless of its previous value.

Flags:　　　**C:**　　Cleared to "0".

No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	CF

Example:　　Given: C = "1" or "0":

The instruction RCF clears the carry flag (C) to logic zero.

RET — Return

RET

Operation: PC ← @SP

SP ← SP + 2

The RET instruction is normally used to return to the previously executing procedure at the end of a procedure entered by a CALL instruction. The contents of the location addressed by the stack pointer are popped into the program counter. The next statement that is executed is the one that is addressed by the new program counter value.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	8 (internal stack)	AF
		10 (external stack)	

Example: Given: SP = 00FCH, (SP) = 101AH, and PC = 1234:

RET   →   PC = 101AH, SP = 00FEH

The statement "RET" pops the contents of stack pointer location 00FCH (10H) into the high byte of the program counter. The stack pointer then pops the value in location 00FEH (1AH) into the PC's low byte and the instruction at location 101AH is executed. The stack pointer now points to memory location 00FEH.

SAMSUNG
ELECTRONICS

RL — Rotate Left

RL   dst

Operation: C ← dst (7)

dst (0) ← dst (7)

dst (n + 1) ← dst (n), n = 0–6

The contents of the destination operand are rotated left one bit position. The initial value of bit 7 is moved to the bit zero (LSB) position and also replaces the carry flag.
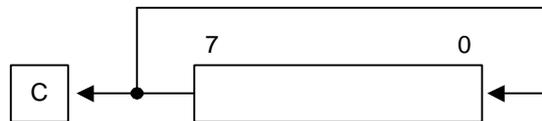

Flags: **C:** Set if the bit rotated from the most significant bit position (bit 7) was "1".
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	**Cycles**	**Opcode (Hex)**	**Addr Mode dst**
opc	dst	2	4	90	R
			4	91	IR

Examples: Given: Register 00H = 0AAH, register 01H = 02H and register 02H = 17H:

RL   00H   →   Register 00H = 55H, C = "1"

RL   @01H   →   Register 01H = 02H, register 02H = 2EH, C = "0"

In the first example, if general register 00H contains the value 0AAH (10101010B), the statement "RL 00H" rotates the 0AAH value left one bit position, leaving the new value 55H (01010101B) and setting the carry and overflow flags.

RLC — **Rotate Left Through Carry**

RLC dst

Operation: dst (0) ← C

C ← dst (7)

dst (n + 1) ← dst (n), n = 0–6

The contents of the destination operand with the carry flag are rotated left one bit position. The initial value of bit 7 replaces the carry flag (C); the initial value of the carry flag replaces bit zero.
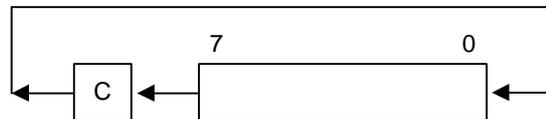

Flags: **C:** Set if the bit rotated from the most significant bit position (bit 7) was "1".
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the sign of the destination changed during rotation; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	4	10	R
			4	11	IR

Examples: Given: Register 00H = 0AAH, register 01H = 02H, and register 02H = 17H, C = "0":

RLC 00H → Register 00H = 54H, C = "1"

RLC @01H → Register 01H = 02H, register 02H = 2EH, C = "0"

In the first example, if general register 00H has the value 0AAH (10101010B), the statement "RLC 00H" rotates 0AAH one bit position to the left. The initial value of bit 7 sets the carry flag and the initial value of the C flag replaces bit zero of register 00H, leaving the value 55H (01010101B). The MSB of register 00H resets the carry flag to "1" and sets the overflow flag.

SAMSUNG
ELECTRONICS

RR — Rotate Right

RR   dst

Operation: C ← dst (0)

dst (7) ← dst (0)

dst (n) ← dst (n + 1), n = 0–6

The contents of the destination operand are rotated right one bit position. The initial value of bit zero (LSB) is moved to bit 7 (MSB) and also replaces the carry flag (C).

```
            ┌────────────────────────────┐
            │        7              0     │
   ┌───┐    │    ┌─────────────────────┐
   │ C │◄──►●──►│                     │
   └───┘        └─────────────────────┘
```

Flags: **C:** Set if the bit rotated from the least significant bit position (bit zero) was "1".
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the sign of the destination changed during rotation; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	4	E0	R
			4	E1	IR

Examples: Given: Register 00H = 31H, register 01H = 02H, and register 02H = 17H:

RR   00H   →   Register 00H = 98H, C = "1"

RR   @01H   →   Register 01H = 02H, register 02H = 8BH, C = "1"

In the first example, if general register 00H contains the value 31H (00110001B), the statement "RR 00H" rotates this value one bit position to the right. The initial value of bit zero is moved to bit 7, leaving the new value 98H (10011000B) in the destination register. The initial bit zero also resets the C flag to "1" and the sign flag and overflow flag are also set to "1".

RRC — Rotate Right Through Carry

RRC   dst

Operation: dst (7) ← C

C ← dst (0)

dst (n) ← dst (n + 1), n = 0–6

The contents of the destination operand and the carry flag are rotated right one bit position. The initial value of bit zero (LSB) replaces the carry flag; the initial value of the carry flag replaces bit 7 (MSB).
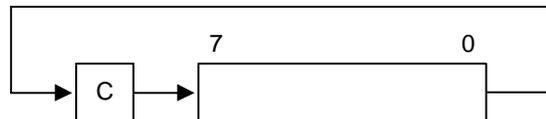

Flags: **C:** Set if the bit rotated from the least significant bit position (bit zero) was "1".
Z: Set if the result is "0" cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the sign of the destination changed during rotation; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc | dst	2	4	C0	R
		4	C1	IR

Examples: Given: Register 00H = 55H, register 01H = 02H, register 02H = 17H, and C = "0":

RRC   00H   →   Register 00H = 2AH, C = "1"

RRC   @01H   →   Register 01H = 02H, register 02H = 0BH, C = "1"

In the first example, if general register 00H contains the value 55H (01010101B), the statement "RRC 00H" rotates this value one bit position to the right. The initial value of bit zero ("1") replaces the carry flag and the initial value of the C flag ("1") replaces bit 7. This leaves the new value 2AH (00101010B) in destination register 00H. The sign flag and overflow flag are both cleared to "0".

SB0 — Select Bank 0

SB0

Operation: BANK ← 0

The SB0 instruction clears the bank address flag in the FLAGS register (FLAGS.0) to logic zero, selecting bank 0 register addressing in the set 1 area of the register file.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	4F

Example: The statement

SB0

clears FLAGS.0 to "0", selecting bank 0 register addressing.

SB1 — Select Bank 1

SB1

Operation: BANK ← 1

The SB1 instruction sets the bank address flag in the FLAGS register (FLAGS.0) to logic one, selecting bank 1 register addressing in the set 1 area of the register file. (Bank 1 is not implemented in some KS88-series microcontrollers.)

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	5F

Example: The statement

SB1

sets FLAGS.0 to "1", selecting bank 1 register addressing, if implemented.

SBC — Subtract With Carry

SBC   dst,src

Operation: dst ← dst − src − c

The source operand, along with the current value of the carry flag, is subtracted from the destination operand and the result is stored in the destination. The contents of the source are unaffected. Subtraction is performed by adding the two's-complement of the source operand to the destination operand. In multiple precision arithmetic, this instruction permits the carry ("borrow") from the subtraction of the low-order operands to be subtracted from the subtraction of high-order operands.

Flags: **C:** Set if a borrow occurred (src > dst); cleared otherwise.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the operands were of opposite sign and the sign of the result is the same as the sign of the source; cleared otherwise.
D: Always set to "1".
H: Cleared if there is a carry from the most significant bit of the low-order four bits of the result; set otherwise, indicating a "borrow".

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc | dst | src	2	4	32	r	r
		6	33	r	lr
opc | src | dst	3	6	34	R	R
		6	35	R	IR
opc | dst | src	3	6	36	R	IM

Examples: Given: R1 = 10H, R2 = 03H, C = "1", register 01H = 20H, register 02H = 03H, and register 03H = 0AH:

SBC   R1,R2   →   R1 = 0CH, R2 = 03H

SBC   R1,@R2   →   R1 = 05H, R2 = 03H, register 03H = 0AH

SBC   01H,02H   →   Register 01H = 1CH, register 02H = 03H

SBC   01H,@02H   →   Register 01H = 15H,register 02H = 03H, register 03H = 0AH

SBC   01H,#8AH   →   Register 01H = 95H; C, S, and V = "1"

In the first example, if working register R1 contains the value 10H and register R2 the value 03H, the statement "SBC R1,R2" subtracts the source value (03H) and the C flag value ("1") from the destination (10H) and then stores the result (0CH) in register R1.

SCF — Set Carry Flag

SCF

Operation: C ← 1

The carry flag (C) is set to logic one, regardless of its previous value.

Flags: **C:** Set to "1".

No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	DF

Example: The statement

SCF

sets the carry flag to logic one.

SAMSUNG
ELECTRONICS

SRA — Shift Right Arithmetic

SRA   dst

Operation: dst (7) ← dst (7)

C ← dst (0)

dst (n) ← dst (n + 1), n = 0–6

An arithmetic shift-right of one bit position is performed on the destination operand. Bit zero (the LSB) replaces the carry flag. The value of bit 7 (the sign bit) is unchanged and is shifted into bit position 6.
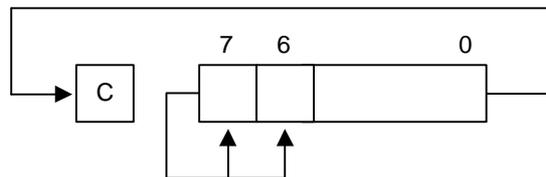

Flags: **C:** Set if the bit shifted from the LSB position (bit zero) was "1".
                   Z: Set if the result is "0"; cleared otherwise.
                   S: Set if the result is negative; cleared otherwise.
                   V: Always cleared to "0".
                   D: Unaffected.
                   H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	4	D0	R
			4	D1	IR

Examples: Given: Register 00H = 9AH, register 02H = 03H, register 03H = 0BCH, and C = "1":

SRA   00H   →   Register 00H = 0CD, C = "0"

SRA   @02H   →   Register 02H = 03H, register 03H = 0DEH, C = "0"

In the first example, if general register 00H contains the value 9AH (10011010B), the statement "SRA 00H" shifts the bit values in register 00H right one bit position. Bit zero ("0") clears the C flag and bit 7 ("1") is then shifted into the bit 6 position (bit 7 remains unchanged). This leaves the value 0CDH (11001101B) in destination register 00H.

SRP/SRP0/SRP1 — **Set Register Pointer**

SRP   src

SRP0   src

SRP1   src

Operation: If src (1) = 1 and src (0) = 0 then: RP0 (3–7) ← src (3–7)

                 If src (1) = 0 and src (0) = 1 then: RP1 (3–7) ← src (3–7)

                 If src (1) = 0 and src (0) = 0 then: RP0 (4–7) ← src (4–7),

                                                   RP0 (3)   ← 0

                                                   RP1 (4–7) ← src (4–7),

                                                   RP1 (3)   ← 1

                 The source data bits one and zero (LSB) determine whether to write one or both of the register pointers, RP0 and RP1. Bits 3–7 of the selected register pointer are written unless both register pointers are selected. RP0.3 is then cleared to logic zero and RP1.3 is set to logic one.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode <u>src</u>
opc | src	2	4	31	IM

Examples: The statement

                 SRP #40H

                 sets register pointer 0 (RP0) at location 0D6H to 40H and register pointer 1 (RP1) at location 0D7H to 48H.

                 The statement "SRP0 #50H" sets RP0 to 50H, and the statement "SRP1 #68H" sets RP1 to 68H.

SAMSUNG
ELECTRONICS

STOP — Stop Operation

STOP

Operation:

The STOP instruction stops the both the CPU clock and system clock and causes the microcontroller to enter Stop mode. During Stop mode, the contents of on-chip CPU registers, peripheral registers, and I/O port control and data registers are retained. Stop mode can be released by an external reset operation or by external interrupts. For the reset operation, the RESET pin must be held to Low level until the required oscillation stabilization interval has elapsed.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	1	4	7F	–	–

Example: The statement

STOP
NOP
NOP
NOP

halts all microcontroller operations.

SUB — Subtract

SUB   dst,src

Operation: dst ← dst − src

The source operand is subtracted from the destination operand and the result is stored in the destination. The contents of the source are unaffected. Subtraction is performed by adding the two's complement of the source operand to the destination operand.

Flags: **C:** Set if a "borrow" occurred; cleared otherwise.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the operands were of opposite signs and the sign of the result is of the same as the sign of the source operand; cleared otherwise.
D: Always set to "1".
H: Cleared if there is a carry from the most significant bit of the low-order four bits of the result; set otherwise indicating a "borrow".

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src	2	4	22	r	r
			6	23	r	Ir
opc	src	dst	3	6	24	R	R
			6	25	R	IR
opc	dst	src	3	6	26	R	IM

Examples: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

SUB   R1,R2   →   R1 = 0FH, R2 = 03H

SUB   R1,@R2   →   R1 = 08H, R2 = 03H

SUB   01H,02H   →   Register 01H = 1EH, register 02H = 03H

SUB   01H,@02H   →   Register 01H = 17H, register 02H = 03H

SUB   01H,#90H   →   Register 01H = 91H; C, S, and V = "1"

SUB   01H,#65H   →   Register 01H = 0BCH; C and S = "1", V = "0"

In the first example, if working register R1 contains the value 12H and if register R2 contains the value 03H, the statement "SUB R1,R2" subtracts the source value (03H) from the destination value (12H) and stores the result (0FH) in destination register R1.

SAMSUNG
ELECTRONICS

SWAP — Swap Nibbles

SWAP   dst

Operation: dst (0 − 3) ↔ dst (4 − 7)

The contents of the lower four bits and upper four bits of the destination operand are swapped.

```
          7       4 3      0
        ┌────────┬────────┐
        │        │        │
        └────────┴────────┘
```
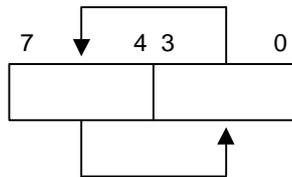

Flags: **C:** Undefined.
                Z: Set if the result is "0"; cleared otherwise.
                S: Set if the result bit 7 is set; cleared otherwise.
                V: Undefined.
                D: Unaffected.
                H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc dst	2	4	F0	R
		4	F1	IR

Examples: Given: Register 00H = 3EH, register 02H = 03H, and register 03H = 0A4H:

SWAP   00H   →   Register 00H = 0E3H
SWAP   @02H   →   Register 02H = 03H, register 03H = 4AH

In the first example, if general register 00H contains the value 3EH (00111110B), the statement "SWAP 00H" swaps the lower and upper four bits (nibbles) in the 00H register, leaving the value 0E3H (11100011B).

TCM — Test Complement Under Mask

TCM   dst,src

Operation: (NOT dst) AND src

This instruction tests selected bits in the destination operand for a logic one value. The bits to be tested are specified by setting a "1" bit in the corresponding position of the source operand (mask). The TCM statement complements the destination operand, which is then ANDed with the source mask. The zero (Z) flag can then be checked to determine the result. The destination and source operands are unaffected.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Always cleared to "0".
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src		2	4	62	r	r
				6	63	r	lr
opc	src	dst	3	6	64	R	R
				6	65	R	IR
opc	dst	src	3	6	66	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 12H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

TCM   R0,R1   →   R0 = 0C7H, R1 = 02H, Z = "1"

TCM   R0,@R1   →   R0 = 0C7H, R1 = 02H, register 02H = 23H, Z = "0"

TCM   00H,01H   →   Register 00H = 2BH, register 01H = 02H, Z = "1"

TCM   00H,@01H   →   Register 00H = 2BH, register 01H = 02H, register 02H = 23H, Z = "1"

TCM   00H,#34   →   Register 00H = 2BH, Z = "0"

In the first example, if working register R0 contains the value 0C7H (11000111B) and register R1 the value 02H (00000010B), the statement "TCM R0,R1" tests bit one in the destination register for a "1" value. Because the mask value corresponds to the test bit, the Z flag is set to logic one and can be tested to determine the result of the TCM operation.

TM — Test Under Mask

TM   dst,src

Operation: dst AND src

This instruction tests selected bits in the destination operand for a logic zero value. The bits to be tested are specified by setting a "1" bit in the corresponding position of the source operand (mask), which is ANDed with the destination operand. The zero (Z) flag can then be checked to determine the result. The destination and source operands are unaffected.

Flags: **C:** Unaffected.
               Z: Set if the result is "0"; cleared otherwise.
               S: Set if the result bit 7 is set; cleared otherwise.
               V: Always reset to "0".
               D: Unaffected.
               H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc dst | src	2	4	72	r	r
		6	73	r	Ir
opc src dst	3	6	74	R	R
		6	75	R	IR
opc dst src	3	6	76	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 18H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

TM   R0,R1   →   R0 = 0C7H, R1 = 02H, Z = "0"

TM   R0,@R1   →   R0 = 0C7H, R1 = 02H, register 02H = 23H, Z = "0"

TM   00H,01H   →   Register 00H = 2BH, register 01H = 02H, Z = "0"

TM   00H,@01H   →   Register 00H = 2BH, register 01H = 02H,
                            register 02H = 23H, Z = "0"

TM   00H,#54H   →   Register 00H = 2BH, Z = "1"

In the first example, if working register R0 contains the value 0C7H (11000111B) and register R1 the value 02H (00000010B), the statement "TM R0,R1" tests bit one in the destination register for a "0" value. Because the mask value does not match the test bit, the Z flag is cleared to logic zero and can be tested to determine the result of the TM operation.

WFI — Wait For Interrupt

WFI

Operation:

The CPU is effectively halted until an interrupt occurs, except that DMA transfers can still take place during this wait state. The WFI status can be released by an internal interrupt, including a fast interrupt .

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4n	3F

(n = 1, 2, 3, …)

Example: The following sample program structure shows the sequence of operations that follow a "WFI" statement:

```
                Main program
                  .
                  .
                  .
                EI              (Enable global interrupt)
                WFI             (Wait for interrupt)
                (Next instruction)
                  .
                  .
                  .
                Interrupt occurs

                Interrupt service routine
                  .
                  .
                  .
                Clear interrupt flag
                IRET

                Service routine completed
```

SAMSUNG
ELECTRONICS
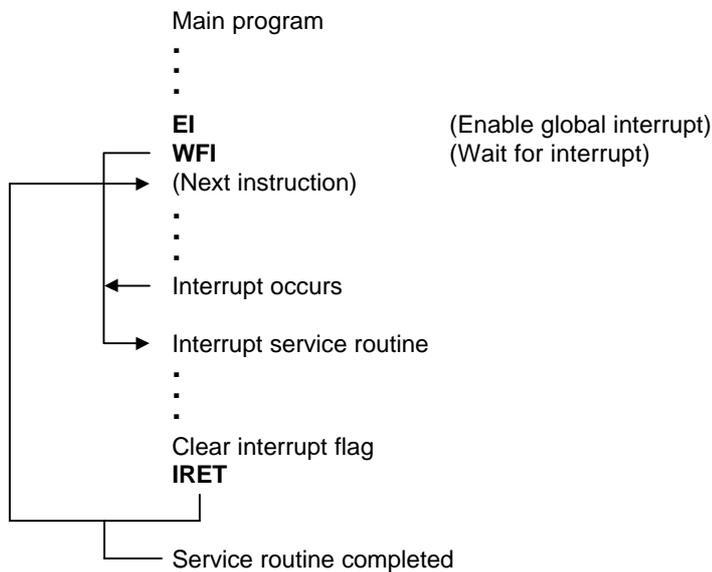

XOR — Logical Exclusive OR

XOR   dst,src

Operation: dst ← dst XOR src

The source operand is logically exclusive-ORed with the destination operand and the result is stored in the destination. The exclusive-OR operation results in a "1" bit being stored whenever the corresponding bits in the operands are different; otherwise, a "0" bit is stored.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Always reset to "0".
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src		2	4	B2	r	r
				6	B3	r	lr
opc	src	dst	3	6	B4	R	R
				6	B5	R	IR
opc	dst	src	3	6	B6	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 18H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

XOR   R0,R1   →   R0 = 0C5H, R1 = 02H

XOR   R0,@R1   →   R0 = 0E4H, R1 = 02H, register 02H = 23H

XOR   00H,01H   →   Register 00H = 29H, register 01H = 02H

XOR   00H,@01H   →   Register 00H = 08H, register 01H = 02H, register 02H = 23H

XOR   00H,#54H   →   Register 00H = 7FH

In the first example, if working register R0 contains the value 0C7H and if register R1 contains the value 02H, the statement "XOR R0,R1" logically exclusive-ORs the R1 value with the R0 value and stores the result (0C5H) in the destination register R0.

NOTES

7 CLOCK CIRCUIT

OVERVIEW

The clock frequency generated for S3C8639/C863A/C8647 by an external crystal ranges from 8 MHz to 12 MHz. The maximum CPU clock frequency is 12 MHz. The X_{IN} and X_{OUT} pins connect the external oscillator or clock source to the on-chip clock circuit.

SYSTEM CLOCK CIRCUIT

The system clock circuit has the following components:

— External crystal or ceramic resonator oscillation source (or an external clock source)

— Oscillator stop and wake-up functions

— Programmable frequency divider for the CPU clock (f_{OSC} divided by 1, 2, 8, or 16)

— System clock control register, CLKCON
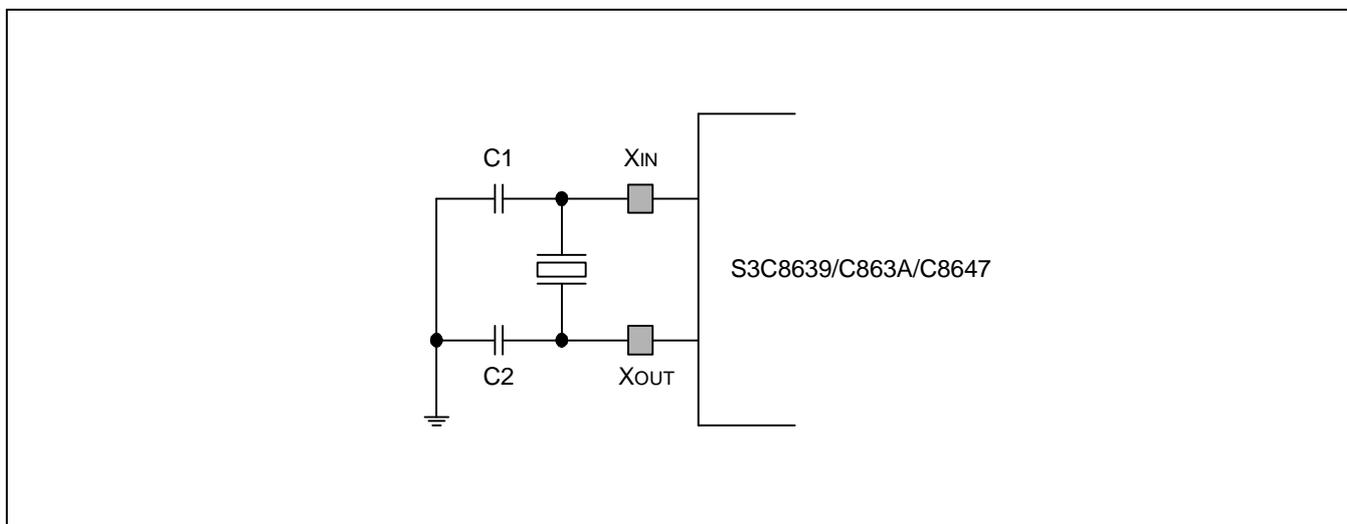

Figure 7-1. Main Oscillator Circuit
(External Crystal or Ceramic Resonator)

CLOCK STATUS DURING POWER-DOWN MODES

The two power-down modes, Stop mode and Idle mode, affect the system clock as follows:

— In Stop mode, the main oscillator is halted. Stop mode is released and the oscillator is started by a reset operation or an external interrupt (with RC delay noise filter).

— In Idle mode, the internal clock signal is gated to the CPU, but not to interrupt structure, timers and timer/counters, and the IIC-bus interface functions. Idle mode is released by a reset or by an external or internal interrupt.
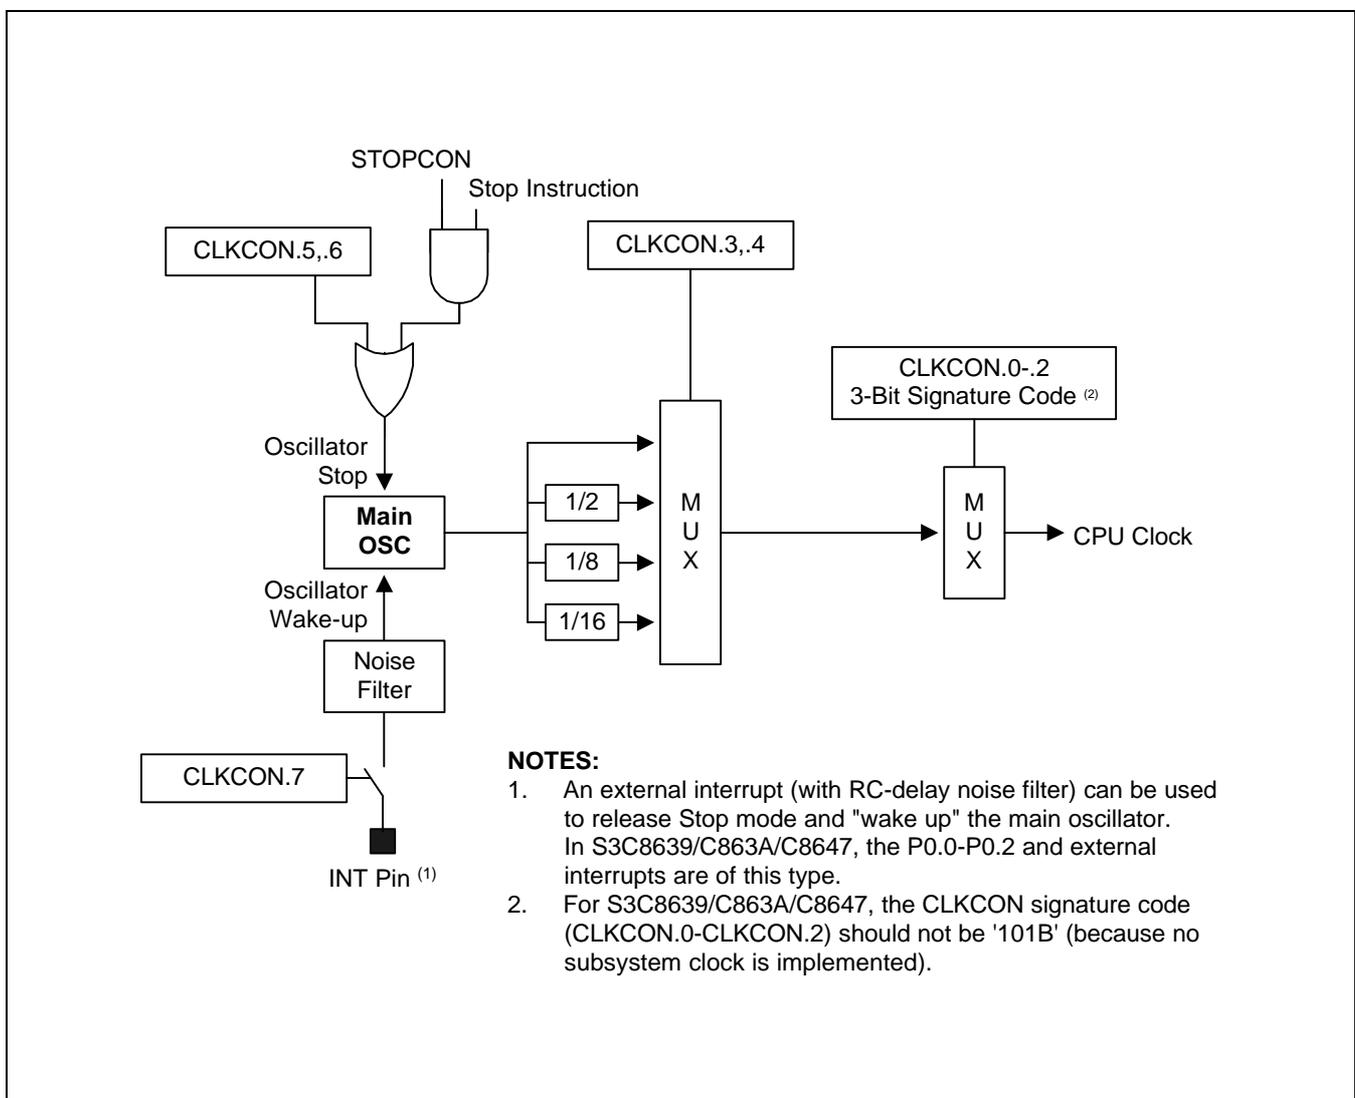

Figure 7-2. System Clock Circuit Diagram

SYSTEM CLOCK CONTROL REGISTER (CLKCON)

The system clock control register, CLKCON, is located in set 1, address D4H. It is read/write addressable and has the following functions:

— Oscillator IRQ wake-up function enable/disable

— Main oscillator stop control

— Oscillator frequency divide-by value

— System clock signal selection

The CLKCON register controls whether or not an external interrupt can be used to trigger a power down mode release. (This is called the "IRQ wake-up" function.) The IRQ wake-up enable bit is CLKCON.7.

After a reset, the external interrupt oscillator wake-up function is enabled, the main oscillator is activated, and the f_{OSC}/16 (the slowest clock speed) is selected as the CPU clock. If necessary, you can raise the CPU clock speed to f_{OSC}, f_{OSC}/2, or f_{OSC}/8.

For the S3C8639/C863A/C8647 microcontrollers, the CLKCON.2–CLKCON.0 system clock signature code must be any value *other than* "101B". (The "101B" setting is invalid because a subsystem clock is not implemented.) The reset value for the clock signature code is "000B" and should remain so during the normal operation.

System Clock Control Register (CLKCON)
D4H, Set 1, R/W

MSB | .7 | .6 | .5 | .4 | .3 | .2 | .1 | .0 | LSB

Oscillator IRQ wake-up enable bit:
0 = Enable IRQ for main system oscillator
    wake-up function in power down mode
1 = Disable IRQ for main system oscillator
    wake-up function in power down mode

System clock selection bits:
101B = Invalid selection
Others = Normal operating mode

Divide-by selection bits for CPU clock frequency:
00 = fosc/16
01 = fosc/8
10 = fosc/2
11 = fosc (non-divided)

Main oscillator stop control bits:
00 = No effect
01 = No effect
10 = stop main oscillator
11 = No effect

Figure 7-3. System Clock Control Register (CLKCON)

NOTES

8 RESET and POWER-DOWN

SYSTEM RESET

OVERVIEW

During a power-on reset, the voltage at V_{DD} goes to High level and the RESET pin is forced to Low level.

The RESET signal is input through a schmitt trigger circuit where it is then synchronized with the CPU clock. This procedure brings S3C8639/C863A/C8647 into a known operating status.

To spare time for internal CPU clock oscillation to stabilize, the RESET pin must be held to Low level for a minimum time interval after the power supply comes within tolerance. The minimum required time for oscillation stabilization in a reset operation is 1 millisecond.

Whenever a reset occurs during the normal operation (that is, when both V_{DD} and RESET are at High level), the RESET pin is forced Low and the reset operation starts. All system and peripheral control registers are then reset to their default hardware values (see Tables 8-1, 8-2, and 8-3).

In summary, the following sequence of events occurs during a reset operation:

— All interrupts are disabled.

— The watchdog function (basic timer) is enabled.

— Ports 0–3 are set to input mode.

— Peripheral control and data registers are disabled and reset to their default hardware values.

— The program counter (PC) is loaded with the program reset address in the ROM, 0100H.

— When the programmed oscillation stabilization time interval has elapsed, the instruction stored in the ROM location 0100H (and 0101H) is fetched and executed.

NOTE

To program the duration of the oscillation stabilization interval, you should make the settings appropriate to the basic timer control register, BTCON, *before* entering Stop mode. Also, if you do not want to use the basic timer watchdog function (which causes a system reset if a basic timer counter overflow occurs), you can disable it by writing "1010B" to the upper nibble of BTCON.

HARDWARE RESET VALUES

Tables 8-1, 8-2, and 8-3 list the reset values for CPU and system registers, peripheral control registers, and peripheral data registers after a reset operation. The following notation is used to represent reset values:

— A "1" or a "0" shows the reset bit value as logic one or logic zero, respectively.

— An "x" means that the bit value is undefined after a reset.

— A dash ("–") means that the bit is either not used or not mapped.

Table 8-1. Set 1 Register Values After Reset

Register Name	Mnemonic	Address		Bit Values After Reset							
		Dec	Hex	7	6	5	4	3	2	1	0
Timer M0 counter register	TM0CNT	208	D0H	0	0	0	0	0	0	0	0
Timer M0 data register	TM0DATA	209	D1H	0	0	0	0	0	0	0	0
Timer M0 control register	TM0CON	210	D2H	0	0	0	0	0	0	0	0
Basic timer control register	BTCON	211	D3H	0	0	0	0	0	0	0	0
Clock control register	CLKCON	212	D4H	0	0	0	0	0	0	0	0
System flags register	FLAGS	213	D5H	x	x	x	x	x	x	0	0
Register pointer 0	RP0	214	D6H	1	1	0	0	0	–	–	–
Register pointer 1	RP1	215	D7H	1	1	0	0	1	–	–	–
Stack pointer (high byte)	SPH	216	D8H	x	x	x	x	x	x	x	x
Stack pointer (low byte)	SPL	217	D9H	x	x	x	x	x	x	x	x
Instruction pointer (high byte)	IPH	218	DAH	x	x	x	x	x	x	x	x
Instruction pointer (low byte)	IPL	219	DBH	x	x	x	x	x	x	x	x
Interrupt request register	IRQ	220	DCH	0	0	0	0	0	0	0	0
Interrupt mask register	IMR	221	DDH	x	x	x	x	x	x	x	x
System mode register	SYM	222	DEH	0	–	–	x	x	x	0	0
Page pointer register	PP	223	DFH	0	0	0	0	0	0	0	0

NOTES:
1. As the SYM register is not used for S3C8639/C863A/C8647, SYM.5 should always be "0". If you accidentally write a "1" to this bit during the normal operation, a system malfunction may occur.
2. Except for TM0CNT, TMODATA, and IRQ, all registers in set 1 are read/write addressable.
3. You cannot use a read-only register as a destination field for the instructions OR, AND, LD, and LDB. The read-only registers in the S3C8639/C863A/C8647 register file are: TM0CNT, TM0DATA, IRQ, SYNCRD, TM1CNTH, TM1CNTL, TM1DATAH, TM1DATAL, ADDATA, BTCNT, PWMCNT, and RBDR.
4. Interrupt pending flags that must be cleared by software are noted by shaded table cells.

Slave IIC-bus address register [4]	SIAR	243	F3H	x	x	x	x	x	x	x	–
Slave IIC-bus data shift register [4]	SIDSR	244	F4H	x	x	x	x	x	x	x	x
Locations F5H–FFH are not mapped.											

NOTES:
1. Except for PWMCNT and RBDR, all registers in set 1, bank 1 are read/write addressable.
2. You cannot use a read-only register as a destination field for the instructions OR, AND, LD, and LDB. The read-only registers in the S3C8639/C863A/C8647 register file are: TM0CNT, TM0DATA, IRQ, SYNCRD, TM1CNTH, TM1CNTL, TM1DATAH, TM1DATAL, ADDATA, BTCNT, PWMCNT, and RBDR.
3. Interrupt pending flags that must be cleared by software are noted by shaded table cells.
4. Not used for the S3C8647.

POWER-DOWN MODES

STOP MODE

Stop mode is invoked by the instruction STOP (opcode 7FH) and the stop control register (STOPCON). In Stop mode, the operation of the CPU and all peripherals is halted. That is, the on-chip main oscillator stops and the supply current is reduced to less than 5 µA. All system functions stop when the clock "freezes," but data stored in the internal register file is retained. Stop mode can be released in one of two ways: by a reset or by an external interrupt (with RC delay).

<div align="center">

NOTE

</div>

Do not use stop mode if you are using an external clock source as X_{IN} input must be restricted internally to V_{SS} to reduce current leakage.

Using RESET to Release Stop Mode

Stop mode is released when the RESET signal goes active (High level): all system and peripheral control registers are reset to their default hardware values and the contents of all data registers are retained. A reset operation automatically selects a slow clock (1/16) because CLKCON.3 and CLKCON.4 are cleared to "00B". After the programmed oscillation stabilization interval has elapsed, the CPU starts the system initialization routine by fetching the program instruction stored in the ROM location 0100H (and 0101H).

Using an External Interrupt to Release Stop Mode

Only external interrupts with an RC-delay noise filter circuit can be used to release Stop mode. Which interrupt you can use to release Stop mode in a given situation depends on the microcontroller's current internal operating mode. The external interrupts in the S3C8639/C863A/C8647 interrupt structure that can be used to release Stop mode are:

— External interrupts P0.0 (INT0), P0.1 (INT1), and P0.2 (INT2)

— Timer M0 capture interrupt in capture mode (with rising or falling edge trigger at the TM0CAP pin and Vsync-O from sync-processor.)

Please note the following conditions for Stop mode release:

— If you release Stop mode using an external interrupt, the current values in system and peripheral control registers are unchanged.

— If you use an external interrupt for Stop mode release, you can also program the duration of the oscillation stabilization interval. To do this, you must make the control and clock settings appropriate *before* entering Stop mode.

— If you use an interrupt to release Stop mode, the CLKCON.4 and CLKCON.3 bit-pair setting remains unchanged and the currently selected clock value is used.

— The external interrupt is serviced when the Stop mode release occurs. Following the IRET from the service routine, the instruction right next to the one that initiated Stop mode is executed.

SAMSUNG
ELECTRONICS

IDLE MODE

Idle mode is invoked by the instruction IDLE (opcode 6FH). In Idle mode, CPU operations are halted while some peripherals remain active. In idle mode, the internal clock signal is gated away from the CPU, but all peripherals timers remain active. Port pins retain the mode (input or output) they had at the time Idle mode was entered.

There are two ways to release idle mode:

1. Execute a reset. All system and peripheral control registers are reset to their default values and the contents of all data registers are retained. The reset automatically selects a *slow clock (1/16)* because CLKCON.4 and CLKCON.3 are cleared to "00B". If interrupts are masked, a reset is the only way to release Idle mode.

2. Activate any enabled interrupt, causing Idle mode to be released. When you use an interrupt to release Idle mode, the CLKCON.4 and CLKCON.3 register values remain unchanged, and the *currently selected clock* value is used. The interrupt is then serviced. When the return-from-interrupt (IRET) occurs, the instruction right next to the one that initiated Idle mode is executed.

NOTE

Only external interrupts can be used to release Stop mode. To release idle mode, you can use either an internally-generated or externally-generated interrupt.

☞   **PROGRAMMING TIP — Sample S3C8639/C863A/C8647 Initialization Routine**

The following sample program shows you how to make initial settings for the S3C8639/C863A/C8647 address space, interrupt vectors, and peripheral functions. Program comments guide you through the steps:

```

NOTES

9   I/O PORTS

OVERVIEW

The S3C8639/C863A/C8647 microcontrollers have four I/O ports with a total of 27 pins. And the S3C8647 microcontroller has three I/O port 0 with a total of 19 pins. Each port can be flexibly configured to meet application design requirements. The CPU accesses ports by directly writing or reading port registers. No special I/O instructions are required. Table 9-1 gives you an overview of port functions:

Table 9-1. S3C8639/C863A/C8647 Port Configuration Overview

Port	Configuration Options	Programmability
0	8-bit general I/O port. Alternatively used for external interrupt inputs and for timer M0 input function.	Bit programmable
1 (Only S3C863X)	3-bit I/O port for normal I/O or n-channel open drain output. Alternatively used for IIC-bus clock and data I/O.	Bit programmable
2	8-bit I/O port for normal I/O, PWM push-pull outputs, PWM n-channel open-drain outputs with 5-volt load capability, or Csync signal input.	Bit programmable
3	8-bit general I/O port. Alternatively used as n-channel open-drain, push-pull outputs with 5-volt load capability or for normal input with pull-up resistor. Multiplexed for alternative use as A/D converter inputs, AD0–AD3.	Bit programmable

PORT DATA REGISTERS

Data registers for ports 0–3 have the format shown in Figure 9-1. Table 9-2 gives you an overview of the port data register locations:

Table 9-2. Port Data Register Summary

Register Name	Mnemonic	Decimal	Hex	Location	R/W
Port 0 data register	P0	224	E0H	Set 1, bank 0	R/W
Port 1 data register (only S3C863X)	P1	225	E1H	Set 1, bank 0	R/W
Port 2 data register	P2	226	E2H	Set 1, bank 0	R/W
Port 3 data register	P3	227	E3H	Set 1, bank 0	R/W

I/O Port Data Register Format (n = 0-3)

NOTE: Port 1 is a 3-bit port. Only bits P1.2-P1.0 of the port 1 data register are mapped. All the other S3C8639/C863A I/O ports are 8-bit.
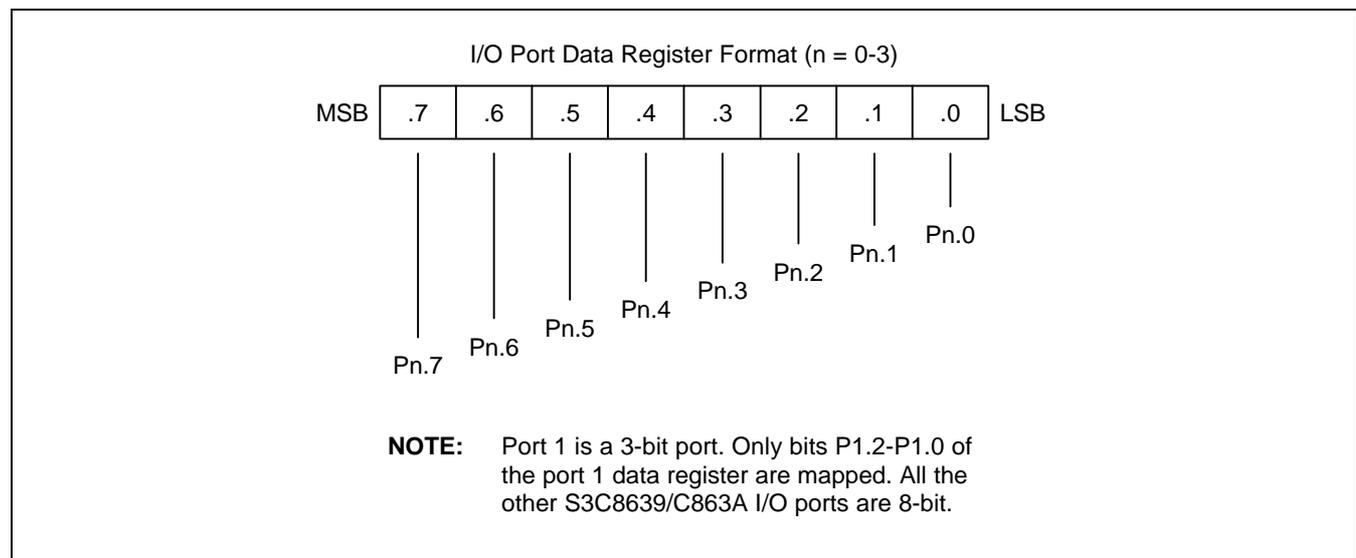

Figure 9-1. Port Data Register Format

PORT 0

Port 0 is an 8-bit I/O port with individually configurable pins. You can directly access port 0 pins by writing or reading the port 0 data register, P0 (set 1, bank 0, E0H). You can use port 0 for general I/O, or for the following alternative functions:

— Low-byte pins (P0.3–P0.0) can be configured as push-pull outputs, while P0.2–P0.0 as a multiplexed input pins for external interrupts INT2–INT0 with rising or falling edge detection.

— High-byte pins (P0.7–P0.4) can be configured as multiplexed inputs and push-pull outputs. P0.4 can serve as the timer M0 capture input pin (TM0CAP).

Two 8-bit control registers are used to configure port 0 pins: P0CONH (set 1, bank 0, E4H) for P0.7–P0.4 and P0CONL (set 1, bank 0, E5H) for P0.3–P0.0. Each byte contains four bit-pairs and each bit-pair configures one pin. The low-byte port 0 control register, P0CONL, is also used to enable and disable the external interrupts, INT2–INT0, at pins P0.2–P0.0, respectively.

SAMSUNG
ELECTRONICS

Port 0 High-Byte Control Register (P0CONH)

The four bit-pairs in the port 0 high-byte control register, P0CONH, have the following functions:

— To configure individual port 0 pins to multiplexed input mode or push-pull output mode.

— To configure alternative input or output functions for P0.7–P0.4.

Bit-pair 1/0 configures the capture signal input pin for timer M0 at P0.4.

SAMSUNG
ELECTRONICS

Port 0 External Interrupt Control Register (P0INT)

The port 0 external interrupt control register, P0INT, is used to enable and disable the external interrupts INT2–INT0 at P0.2–P0.0, respectively, and also to detect and clear external interrupt pending conditions at these pins.

To selectively enable the external interrupts INT0, INT1, and INT2, you set P0INT.0, P0INT.1, and P0INT.2 to "1", respectively. The application program can poll the corresponding interrupt pending bits — P0INT.4 for INT0, P0INT.5 for INT1, and P0INT.6 for INT2 — to detect external interrupt pending conditions.

After an external interrupt has been serviced, the service routine must clear the pending condition by writing a "0" to the appropriate pending bit. Writing a "1" to the pending bit has no effect.

PORT 1 (Only S3C863X)

Port 1 is an 3-bit port with individually configurable pins. You can directly access it by writing or reading the port 1 data register, P1 (set 1, bank 0, E1H). You can use port 1 for normal output, input mode, or n-channel open-drain output mode.

The port 1 control register, P1CON (set 1, bank 0, E6H) is used to configure port 1 pins. Each byte contains four bit-pairs and each bit-pair configures one pin.

Bit pair 3/2 configures the IIC-bus clock pin for SCL1 at P1.1. Bit pair 1/0 controls P1.0 when it is set to "11B", the SDA1 is enabled for IIC-bus data pin.
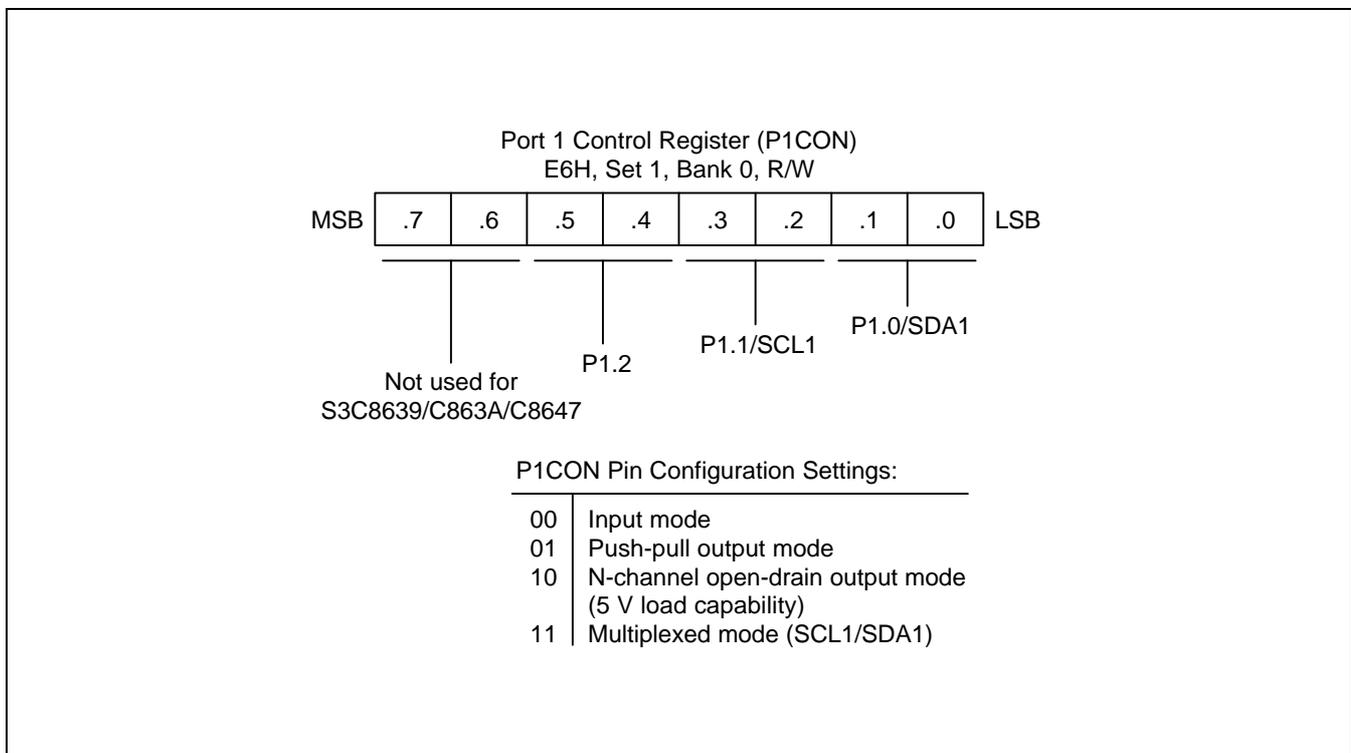

Figure 9-5. Port 1 Control Register (P1CON)

PORT 2

Port 2 is an 8-bit I/O port with individually configurable pins. You can directly access port 2 pins by writing or reading the port 2 data register, P2 (set 1, bank 0, E2H).

Two 8-bit control registers are used to configure port 2 pins: P2CONH (set 1, bank 0, E7H) which let you select digital input mode (or TTL input mode), normal or PWM push-pull output mode, or n-channel open drain PWM output mode. And you can select digital input mode, normal or PWM push-pull output mode at the P2CONL (set 1, bank 0, E8H)

PORT 3

Port 3 is an 8-bit I/O port with individually configurable pins. You can directly access it by writing or reading the port 3 data register, P3 (set 1, bank 0, E3H). You can selectively configure P3 pins to input or output mode. In input mode, you can also select A/D converter input mode (P3.0–P3.3 only) or normal digital input mode (with or without pull-up resistor). Output mode is push-pull mode or n-channel open-drain mode (P3.4–P3.7 only).

Two 8-bit control registers are used to configure port 3 pins: P3CONH (E9H, set 1, bank 0) for P3.7–P3.4 and P3CONL (set 1, bank 0, EAH) for P3.3–P3.0. Each byte contains four bit-pairs and each bit-pair configures one pin.

FUNCTION-FIXED PORT

These I/O pins are used only for the input and output of video synchronization signals to the sync processor or DDC & IIC-bus interface. The horizontal and vertical sync signals can be monitored directly through the Sync Port Read Data Register (SYNCRD).

Sync signal ports

— Csync-I: Composite (SOG) synchronization input port (TTL level)

— Hsync-I: Horizontal synchronization input (TTL level)

— Vsync-I: Vertical synchronization input and synchro clock (VCLK) for DDC1 (TTL level)

— Hsync-O: Horizontal synchronization output from the sync processor

— Vsync-O: Vertical synchronization output from the sync processor

— Clamp-O: Clamp signal output with programmable width from the sync processor

DDC and IIC-bus interface ports

— SDA0: DDC and IIC-bus interface serial data

— SCL0: DDC and IIC-bus interface serial clock

NOTES

10 BASIC TIMER

OVERVIEW

S3C8639/C863A/C8647 has a default timer: an 8-bit *basic timer.*

You can use the basic timer (BT) in two different ways:

— As a watchdog timer, it provides an automatic reset mechanism in the event of a system malfunction.

— Signals the end of the required oscillation stabilization interval after a reset or a Stop mode release.

The functional components of the basic timer block are:

— Clock frequency divider (f_{OSC} divided by 4096, 1024, or 128) with multiplexer

— 8-bit basic timer counter, BTCNT (set 1, bank 0, FDH, read-only)

— Basic timer control register, BTCON (set 1, D3H, read/write)

— Watchdog timer control register, WDTCON (set 1, bank 0, ECH, read/write)

BASIC TIMER CONTROL REGISTER (BTCON)

The basic timer control register, BTCON, is used to select the input clock frequency, to clear the basic timer counter and frequency dividers, and to enable or disable the watchdog timer function. It is located in set 1, address D3H, and is read/write addressable using register addressing mode.

A reset clears BTCON to "00H". This enables the watchdog function and selects a basic timer clock frequency of $f_{OSC}/4096$. To disable the watchdog function, you must write the signature code "1010B" to the basic timer register control bits BTCON.7–BTCON.4.

The 8-bit basic timer counter, BTCNT (set 1, bank 0, FDH), can be cleared at any time during the normal operation by writing a "1" to BTCON.1. To clear the frequency dividers for both the basic timer input clock and the timer M0 clock (unless timer M0 uses an external clock source), you should write a "1" to BTCON.0.

Basic Timer Control Register (BTCON)

Watchdog time enable bits:
1010B = Disable watchdog function
Others = Enable watchdog function

Divider clear bit for BT and T0:
0 = No effect
1 = Clear both dividers
(basic timer, timer M0)

Basic timer/counter clear bit:
0 = No effect
1 = Clear basic timer

Basic timer input clock selection bits:
00 = fosc/4096
01 = fosc/1024
10 = fosc/128
11 = Not used

Figure 10-1. Basic Timer Control Register (BTCON)

WATCHDOG TIME CONTROL REGISTER (WDTCON)

The watchdog time control register, WDTCON, is used to generate various watchdog time and to select Hsync output. It is located in set 1, bank 0, address ECH, and is read/write addressable using register addressing mode.

Watchdog Time Control Register (WDTCON)

Hsync-O divide enable bit:
0 = Hsync-I (Non-divide)
1 = Hsync-I/2

Watchdog time generation control bits:

000	t_{BTOVF}
001	$t_{BTOVF}/2$
010	$t_{BTOVF}/3$
011	$t_{BTOVF}/4$
100	$t_{BTOVF}/5$
101	$t_{BTOVF}/6$
110	$t_{BTOVF}/7$
111	$t_{BTOVF}/8$

NOTE: $t_{BTOVF} = (1/f_{OSC}) \times (\text{divider count of basic timer input clock}) \times 256$
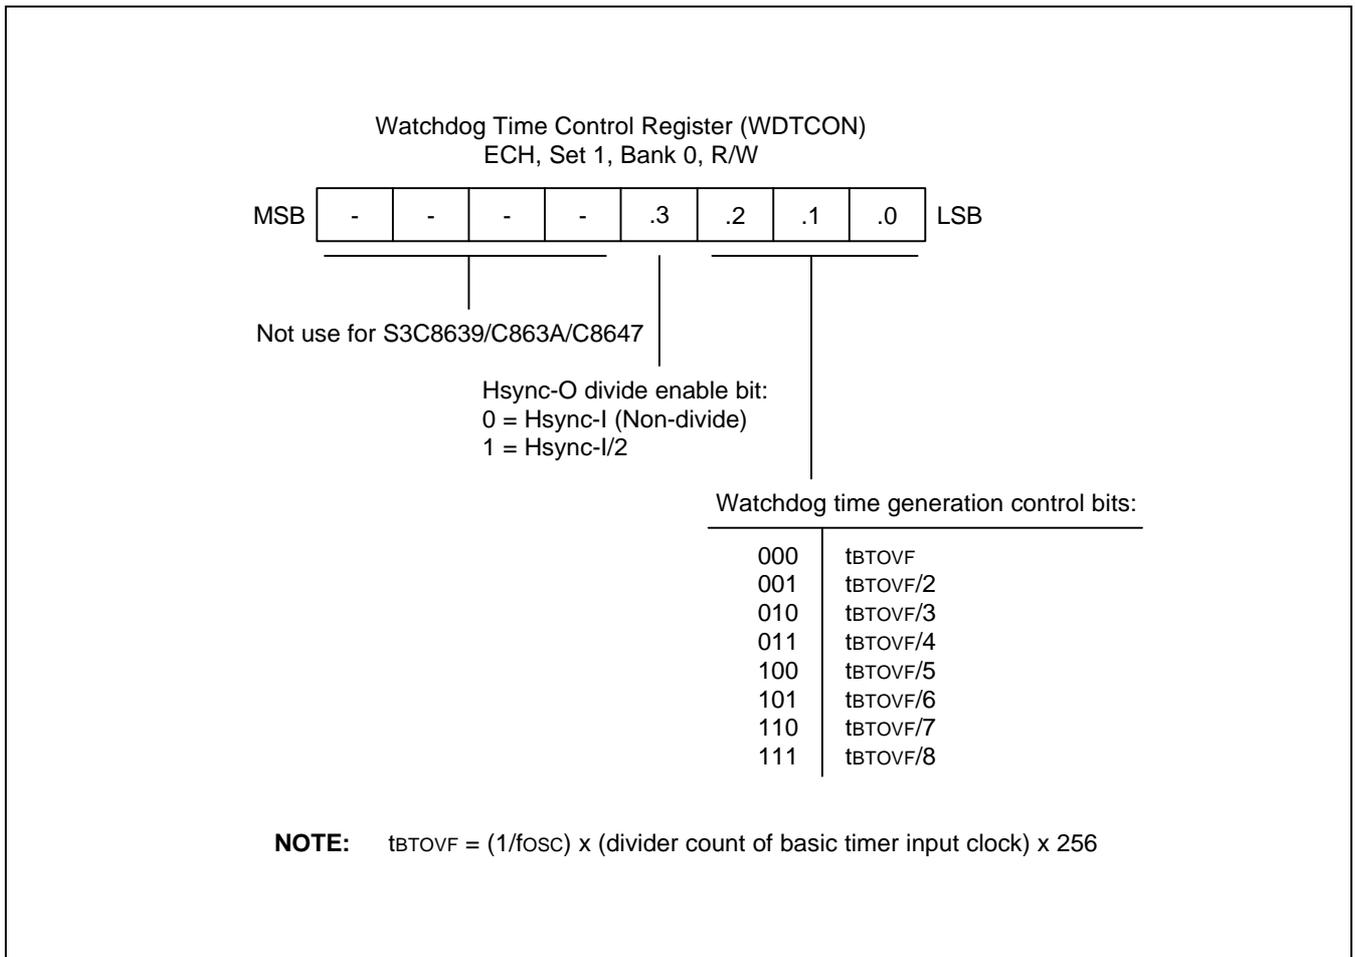

Figure 10-2. Watchdog Time Control Register (WDTCON)

BASIC TIMER FUNCTION DESCRIPTION

Watchdog Timer Function

You can program the basic timer overflow signal (BTOVF) to generate a reset by setting BTCON.7–BTCON.4 to any value other than "1010B" (The "1010B" value disables the watchdog function). A reset clears BTCON to "00H", automatically enabling the watchdog timer function. A reset also selects the CPU clock (as determined by the current CLKCON register setting),divided by 4096, as the BT clock.

A reset whenever a basic timer counter overflow occurs. During the normal operation, the application program must prevent the overflow and the accompanying reset operation from occurring. To do this, the BTCNT value must be cleared (by writing a "1" to BTCON.1) at regular intervals. And you can generate the various watchdog time by setting WDTCON.2-WDTCON.0.

If a system malfunction occurs due to circuit noise or some other error condition, the BT counter clear operation will not be executed and a basic timer overflow will occur, initiating a reset. In other words, during the normal operation, the basic timer overflow loop (a bit 7 overflow of the 8-bit basic timer counter, BTCNT) is always broken by a BTCNT clear instruction. If a malfunction does occur, a reset is triggered automatically.

Oscillation Stabilization Interval Timer Function

You can also use the basic timer to program a specific oscillation stabilization interval after a reset or when stop mode has been released by an external interrupt.

In Stop mode, whenever a reset or an external interrupt occurs, the oscillator starts. The BTCNT value then starts increasing at the rate of f_{OSC}/4096 (for reset), or at the rate of the preset clock source (for an external interrupt). When BTCNT.4 overflows, a signal is generated to indicate that the stabilization interval has elapsed and to gate the clock signal off to the CPU so that it can resume the normal operation.

In summary, the following events occur when Stop mode is released:

1. During the stop mode, a power-on reset or an external interrupt occurs to trigger the stop mode release and oscillation starts.

2. If a power-on reset occurred, the basic timer counter would increase at the rate of f_{OSC}/4096. If an external interrupt is used to release Stop mode, the BTCNT value increases at the rate of the preset clock source.

3. Clock oscillation stabilization interval begins and continues until bit 4 of the basic timer counter overflows.

4. When a BTCNT.4 overflow occurs, the normal CPU operation resumes.
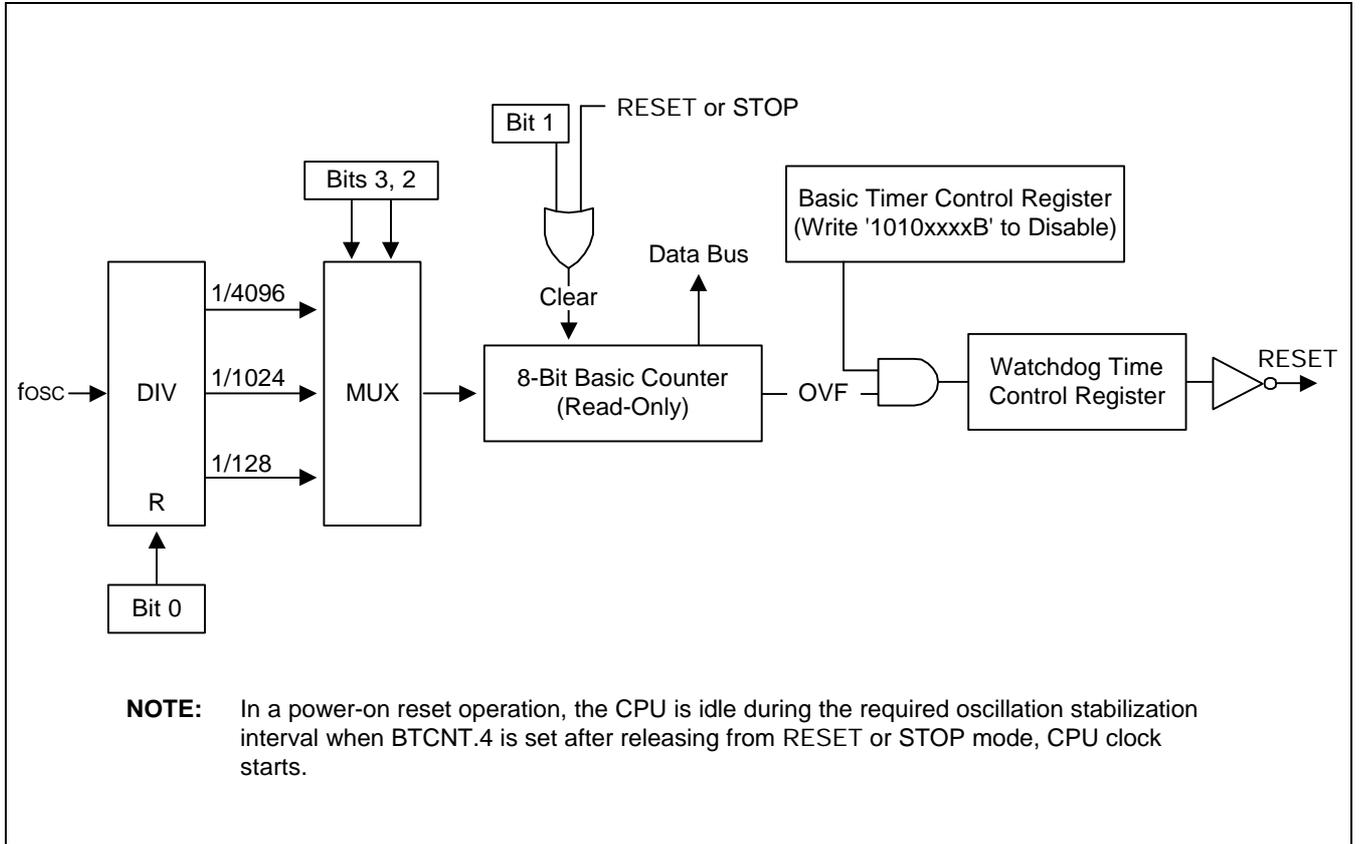

Figure 10-3. Basic Timer Block Diagram

☞ **PROGRAMMING TIP — Configuring the Basic Timer**

This example shows how to configure the basic timer to sample specifications:

```
            ORG     0100H

11 TIMER M0

OVERVIEW

The 8-bit *timer M0* is for monitor application. Timer M0 includes capture timer mode using the appropriate TM0CON setting.

Timer M0 has the following functional components:

— Clock frequency divider (f_{OSC} divided by 128 or 8) with multiplexer

— 2-bit prescaler for the timer M0 input clock

— 8-bit counter (TM0CNT; set1, D0H, read-only) and 8-bit reference data register (TM0DATA; set1, D1H, read-only)

— Timer M0 capture or overflow interrupt (IRQ0, vector E2H, E0H) generation

— Timer M0 control register, TM0CON (set 1, D2H, read/write)

FUNCTION DESCRIPTION

CAPTURE TIMER FUNCTION

The timer M0 module can generate two interrupts: the timer M0 capture interrupt (TM0INT), and the timer M0 overflow interrupt (TM0OVF). TM0INT belongs to interrupt level IRQ0, and is assigned the separate vector address, E2H. TM0OVF is interrupt level IRQ0, vector E0H.

The TM0INT and TM0OVF pending conditions are automatically cleared by hardware after they are serviced.

In capture timer mode, a signal edge that is detected at the TM0CAP pin opens a gate and loads the current counter value into the timer M0 data register (TM0DATA). You can select rising or falling edge to trigger this operation.

Both kinds of timer M0 interrupts can be used in capture mode: the timer M0 overflow interrupt is generated whenever a counter overflow occurs; the timer M0 capture interrupt is generated whenever the counter value is loaded into the timer M0 data register.

By reading captured data value in TM0DATA, and assuming a specific value for the timer M0 clock frequency, you can calculate the internal time of the signal being input to the TM0CAP pin or the vertical sync output signal being output from the sync-processor module.

Timer M0 Control Register (TM0CON)

You use the timer M0 control register, TM0CON, to

— Select the timer M0 operating mode (capture mode)
— Select the timer M0 input clock frequency
— Clear the timer M0 counter, TM0CNT
— Enable the timer M0 overflow interrupt and timer M0 capture interrupt
— Select a 2-bit prescaler value for the Timer M0 input clock
— Select the timer M0 capture input source

TM0CON is located in set 1, at address D2H, and is read/write addressable using Register addressing mode.

A reset clears TM0CON to "00H". This sets timer M0 to disable capture timer mode, selects an input clock frequency of $f_{OSC}/128$, and disables timer M0 overflow and capture interrupts. You can clear the timer M0 counter at any time during the normal operation by writing a "1" to TM0CON.2.

The timer M0 overflow interrupt (TM0OVF) is in the interrupt level IRQ0 and has the vector address E0H. When the timer M0 capture interrupt is disabled, the Timer M0 overflow interrupt by clock (f_{OSC}) is possible. When a timer M0 overflow interrupt occurs and is serviced by the CPU, the pending condition is cleared automatically by hardware.

To enable the timer M0 capture interrupt (IRQ0, vector E2H), you must write TM0CON.1 to "1". There is no pending bit cleared by software or static read bit which is H/W pending. After the interrupt request is serviced, the pending condition is automatically cleared by hardware.
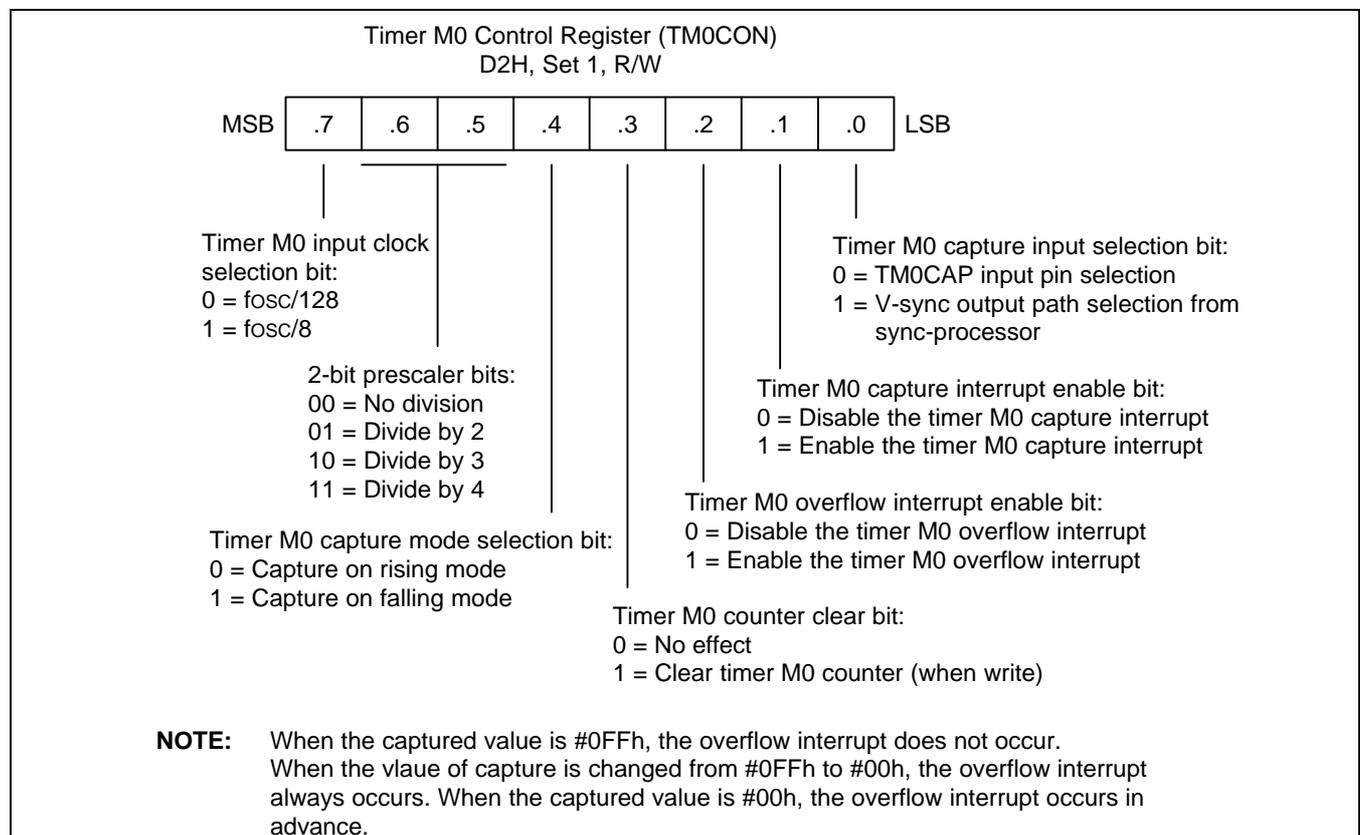

Figure 11-1. Timer M0 Control Register (TM0CON)

BLOCK DIAGRAM
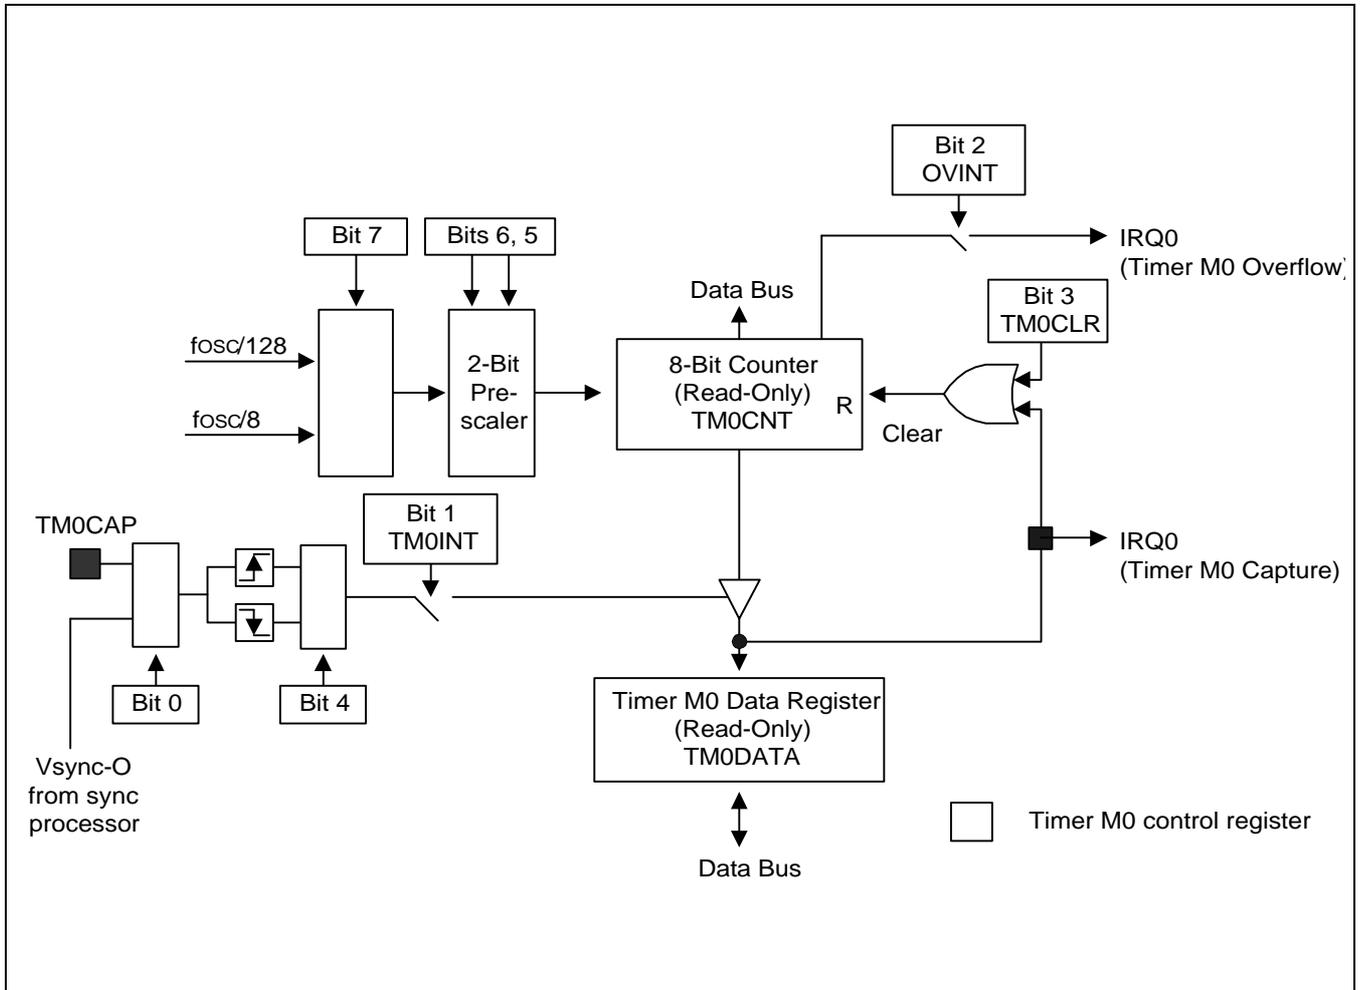

Figure 11-2. Timer M0 Functional Block Diagram

NOTES

12 TIMER M1

OVERVIEW

The 12-bit *timer M1* is an 12-bit timer/counter for monitor application. Timer M1 offers capture/overflow timer mode using the appropriate TM1CON setting.

Timer M1 has the following functional components:

— Clock frequency selector as the timer M1 clock (f_{OSC} divided by 512, 128, or 2, Hsync-I or Csync-I from sync-processor) with multiplexer

— Capture signal selector from V-syncO (sync-processor) or the timer M2 interval time

— 12-bit counter (TM1CNTH, TM1CNTL; set1, bank0, F1H, F2H, read-only) and 12-bit reference data register (TM1DATAH, TM1DATAL; set1, bank0, F3H, F4H, read-only)

— Timer M1 capture or overflow interrupt (IRQ2, vector E8H, E6H) generation

— Timer M1 control register, TM1CON (set 1, bank0, F5H, read/write)

FUNCTION DESCRIPTION

Overflow Timer Function

The timer M1 module generates an overflow signal whenever the timer M1 counter overflow occurs. If you set the timer M1 overflow interrupt enable bit, TM1CON.2, to "1", an interrupt is generated whenever an overflow state is detected. After the interrupt request is generated, the counter register value is cleared and counting resumes from "00H".

The timer M1 overflow interrupt pending condition is automatically cleared by hardware when it has been serviced.

Capture Timer Function

The Timer M1 module can generate, the timer M1 capture interrupt (TM1INT). TM1INT belongs to interrupt level IRQ2, and is assigned the vector address, E8H.

In capture timer mode, a capture signal from Vsync-O (sync-processor) or the timer M2 interval timer opens a gate and loads the current counter value into the timer M1 data register (TM1DATA). You can select Vsync-O or the timer M2 interval timer as the capture signal source to trigger this operation.

By reading captured data value in TM1DATAH and TM1DATAL, and assuming a specific value for the timer M1 clock frequency, you can calculate the frequency of the signal being input to the Hsync-I or Csync-I from sync-processor by capture signal.

Timer M1 Control Register (TM1CON)

You use the timer M1 control register, TM1CON, to

— Select the capture signal source

— Select the timer M1 clock input

— Clear the timer M1 counter, TM1CNTH and TM1CNTL

— Enable the timer M1 capture and overflow interrupt

— Clear the timer M1 capture interrupt pending bit

— Select Vsync-O capture edge as capture signal source (When TM1CON.7 = "1")

TM1CON is located in set 1, bank0, at address F5H, and is read/write addressable using Register addressing mode.

The setting for bit-pair TM1CON.0 and TM1CON.1 selects the timer M1 counter clock input. The timer M1 capture and overflow interrupt (TM1INT, TM1OVF) are in the interrupt level IRQ2, but has the different vector address (E8H, E6H respectively).

TM1CON.4 is the interrupt pending flag for the timer M1 capture interrupt. To clear a timer M1 interrupt pending condition, the interrupt service routine must write a "0" to TM1CON.4 after the CPU has acknowledged the request. TM1CON.3 is flag to clear the 12-bit Timer M1 counter.

TM1CON.7 is flag to select the capture signal source (timer M2 interval time or Vsync-O from sync-processor) and TM1CON.6 is flag to select the capture edge as the Vsync-O capture signal source.

A reset operation clears TM1CON to "00H", selecting the Hsync-I or Csync-l from sync-processor are the timer M1 clock and disabling the timer M1 capture and overflow interrupt.

BLOCK DIAGRAM

Figure 12-2. Timer M1 Functional Block Diagram

13 TIMER M2

OVERVIEW

The interval timer M2 is no-counter timer for monitor application. Timer M2 offers interval timer mode using the appropriate TM1CON setting.

Timer M2 has the following functional components:

— 5-bit scaler by f_{OSC}/1000 for timer M2 interval source

— Timer M1 capture interval time source selector (When TM1CON.5 is "1") with 2-bit scaler

— Timer M2 interval interrupt (IRQ1, vector E4H) generation

— Timer M2 control register, TM2CON (set 1, F6H, read/write)

FUNCTION DESCRIPTION

Interval Timer Function

The timer M2 module generates an interval interrupt whenever the TM2CON.2 is "1". TM2INT belongs to the interrupt level IRQ1, and is assigned the separate vector address, E4H. The TM2INT pending condition is automatically cleared by hardware when it has been serviced.

Timer M2 Control Register (TM2CON)

You use the timer M2 control register, TM2CON, to

— Select the interval time signal source by 5-bit scaler

— Enable the timer M2 interval interrupt

— Select timer M1 capture interval time by 2-bit scaler (When TM1CON.5 = "1")

TM2CON is located in set 1, bank0, at address F6H, and is read/write addressable using Register addressing mode.

A reset operation clears TM2CON to "F8H" (11111000B), thereby setting the 5-bit scaler value to be divided by 32.

Timer M2 Control Register (TM2CON)

5-bit scaler bits:
00000 = No division
00001 = Divide by 2
00010 = Divide by 3
. . .
11111 = Divide by 32

Timer M1 capture interval time
selection bits:
00 = Timer M2 interval (bypass)
01 = Timer M2 interval x 10
10 = Timer M2 interval x 20
11 = Timer M2 interval x30

Timer M2 interval interrupt enable bit:
0 = Disable the timer M2 interval interrupt
1 = Enable the timer M2 interval interrupt

NOTES:
1. When the timer M1 capture mode is enabled (TM1CON.5 = "1"), the value of 5-bit or
   2-bit scaler can be changed only in the timer M1capture interrupt routine.
2. When the timer M1 capture mode is disabled (TM1CON.5 = "0"), the value of 5-bit
   scaler can be changed only in the timer M2 interval interrupt routine.

NOTES

14 ANALOG-TO-DIGITAL CONVERTER

OVERVIEW

The 8-bit A/D converter (ADC) module of S3C8639/C863A/C8647 employs successive approximation logic to convert analog levels entering one of the four input channels to equivalent 8-bit digital values. The analog input level must lie between the V_{DD2} and V_{SS2} values. The A/D converter has the following components:

— Analog comparator with successive approximation logic

— D/A converter logic (resistor string type)

— 8-bit ADC control register (ADCON)

— Four multiplexed analog data input pins (ADC0–ADC3)

— 8-bit A/D conversion data output register (ADDATA) (S3C863X)

— 4-bit A/D conversion data output register (ADDATA) (S3C8647)

— 8-bit digital input port (Alternatively, I/O port)

— V_{DD2} and V_{SS2} pins (S3C863X)

FUNCTION DESCRIPTION

To initiate an analog-to-digital conversion procedure, write the channel selection data in the A/D converter control register ADCON to select one of the four analog input pins (ADCn, n = 0–3) and set the conversion start or enable bit, ADCON.0. The read-write ADCON register is located in set 1, bank0, at address F7H.

During the normal conversion, ADC block initially sets the successive approximation register to 80H (approximately the half-way point of an 8-bit register). This register is then updated automatically in each conversion step. The successive approximation block performs 8-bit conversions for one input channel at a time. You can dynamically select different channels by manipulating the channel selection bit value (ADCON.5–.4) in the ADCON register. To start the A/D conversion, you should set, ADCON.0. When a conversion is completed, ADCON.3, the end-of-conversion (EOC) bit, is automatically set to 1 and the result is dumped into the ADDATA register where it can be read. The A/D converter then enters an idle state. Remember to read the contents of ADDATA before another conversion starts. Otherwise, the previous result will be overwritten by the next conversion result.

NOTE

As the A/D converter does not include any sample-and-hold circuitry, it is very important to keep the fluctuation in the analog level at the ADC0–ADC3 input pins to an absolute minimum during the conversion process. Any change in the input level, perhaps due to noise, will invalidate the result. If the chip enters to STOP or IDLE mode in conversion process, there will be a leakage current path in A/D block. You must use STOP or IDLE mode after A/D converting operation is finished.

CONVERSION TIMING

The A/D conversion process requires 4 steps (8 clock edges) to convert each bit. Therefore, a total of 48 clocks are required to complete an 10-bit conversion. With an 8 MHz f_{OSC} clock frequency, one clock cycle is 1 μs (when ADCON.2, .1 are "01"). If each bit conversion requires 4 clocks, the conversion rate is calculated as follows:

start (4 clocks) + (4 clocks/bit × n bits) + EOC (4 clocks) = 4(n+2) clocks, 1 μs x 4(n+2) = 4(n+2) μs at 8 MHz
where, n = 4 (S3C8647), 10 (S3C863x)

A/D CONVERTER CONTROL REGISTER (ADCON)

The A/D converter control register, ADCON, is located at address F7H in set 1, bank0. It has four functions:

— Analog input pin selection (bits 4,5 and 6)

— End-of-conversion status detection (bit 3)

— Clock source selection (bits 2 and 1)

— A/D operation start or enable (bit 0)

After a reset, the ADC0 pin is automatically selected as the analog data input pin, and the start bit is turned off.

You can select only one analog input channel at a time. Other analog input pins (ADC0–ADC3) can be selected dynamically by manipulating the ADCON.6–.4 bits.

ELECTRONICS

INTERNAL REFERENCE VOLTAGE LEVELS

In the ADC function block, the analog input voltage level is compared to the reference voltage. The analog input level must remain within the range of AV_{SS} (V_{SS2}) to AV_{REF} (V_{DD2}).

Different reference voltage levels are generated internally along the resistor tree during the analog conversion process for each conversion step. The reference voltage level for the first conversion bit is always $1/2\ V_{DD2}$.

NOTES

15 PULSE WIDTH MODULATION

PWM MODULE

The S3C8639/C863A/C8647 microcontrollers include seven 8-bit PWM circuits, PWM0–PWM6. The S3C8647 microcontroller includes six 8-bit PWM circuits, PWM0–PWM5. The operation of all PWM circuits is controlled by a single control register, PWMCON.

The PWM counter, a 8-bit incrementing counter, is used by the 8-bit PWM circuits. To start the counter and enable the PWM circuits, set PWMCON.5 to "1". If the counter is stopped, it retains its current count value. When restarted, it resumes counting from the retained count value.

By modifying the prescaler value, you can divide the input clock by one (non-divided), two, three, or four. The prescaler output is the clock frequency of the PWM counter.

The PWM counter overflows when it reaches "3FH", and then continues counting from zero.

PWM CONTROL REGISTER (PWMCON)

The control register for the PWM module, PWMCON, is located in set 1, bank 1, at register address E7H. You use PWMCON bit settings to control the following functions in the 8-bit:

— PWM counter operation: stop/start (or resume counting)

A reset clears PWMCON to "00H", disabling all PWM functions.

PWM Control Register (PWMCON)

PWM0–PWM6

The S3C8639/C863A/C8647 microcontrollers include seven 8-bit PWM circuits, PWM0–PWM6. The S3C8647 microcontroller include six 8-bit PWM circuits, PWM0–PWM5. Each 8-bit PWM data unit is comprised of an 8-bit basic frame. The 8-bit PWM circuits have the following components:

— 8-bit counter

— 8-bit comparators

— 8-bit PWM data registers (PWM0–PWM5, PWM6 [(note)])

— PWM output pins (PWM0–PWM5, PWM6 [(note)])

The PWM0–PWM6 circuits are controlled by the PWMCON register (set 1, bank 1, E7H).

NOTE: Not used for the S3C8647.
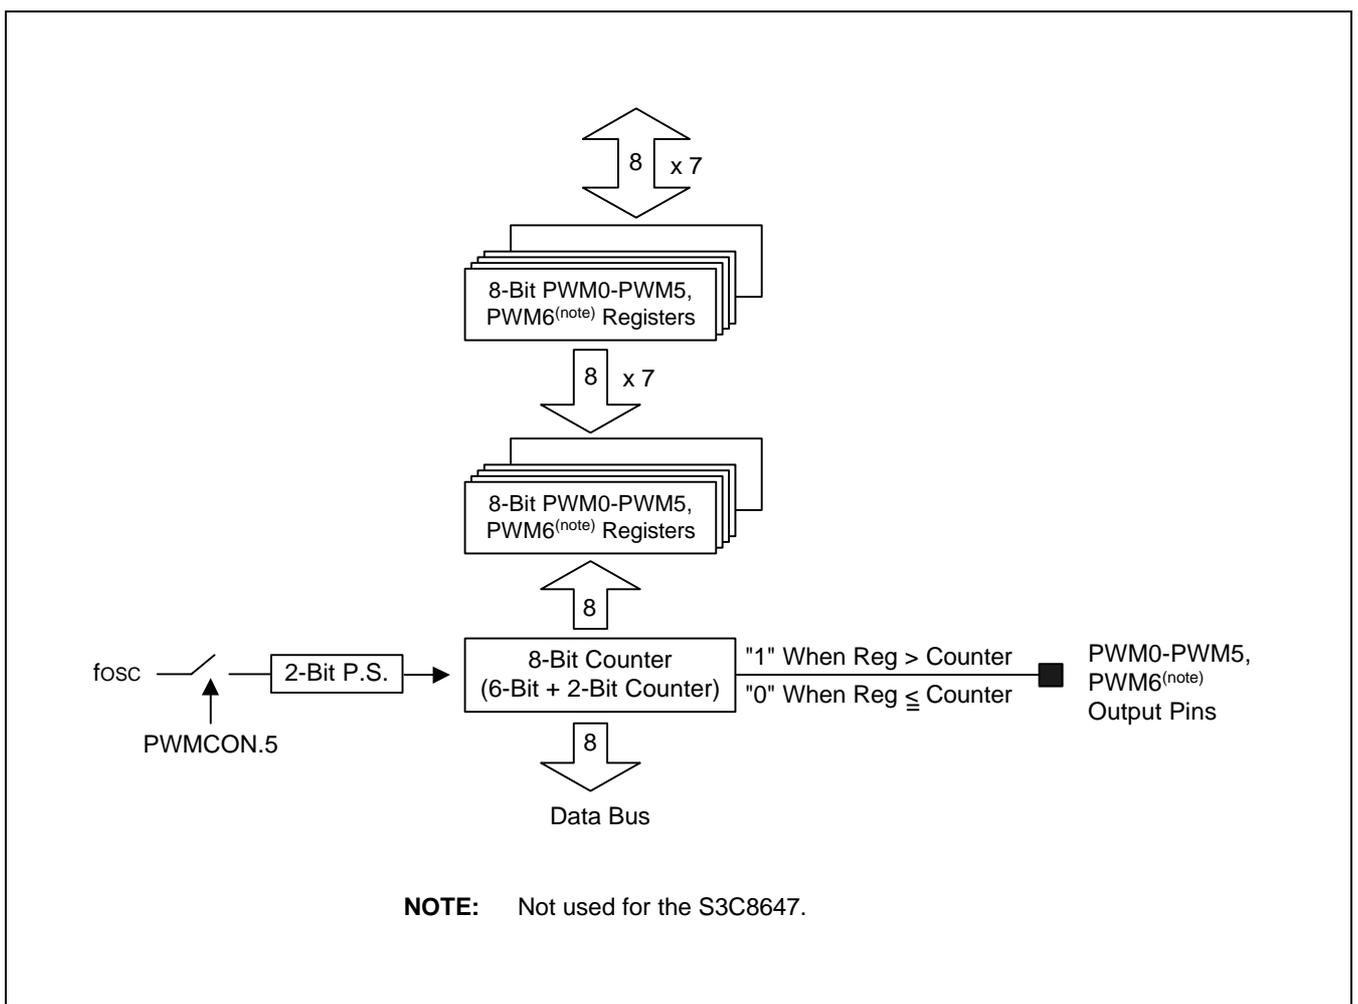

Figure 15-2. Block Diagram for PWM0–PWM6

PWM0–PWM6 FUNCTION DESCRIPTION

All the seven 8-bit PWM circuits have an identical function and each has its own 8-bit data register and 8-bit comparator. Each circuit compares a unique data register value to the 8-bit PWM counter.

The PWM0–PWM6 data registers are located in set 1, bank 1, at locations E0H–E6H, respectively. These data registers are read/write addressable. By loading specific values into the respective data registers, you can modulate the pulse width at the corresponding PWM output pins, PWM0–PWM6. (PWM0–PWM6 correspond to port 2 pins P2.0–P2.6.)

The level at the output pins toggles High and Low at a frequency equal to the counter clock, divided by 64 (2^6). The duty cycle of the 8-bit PWM pins ranges from 0% to 98.44% (63/64), based on the corresponding data register values.

To determine the output duty cycle of an 8-bit PWM circuit, its 8-bit comparator sends the output level High when the data register value is greater than the lower 8-bit count value. The output level is Low when the data register value is less than or equal to the lower 8-bit count value. The output level at the PWM0–PWM6 pins remains at Low level for the first 256 counter clocks. Then, each PWM waveform is repeated continuously, at the same frequency and duty cycle, until one of the following three events occurs:

— The counter is stopped

— The counter clock frequency is changed

— A new value is written to the PWM data register

STAGGERED PWM OUTPUTS

The PWM0–PWM6 outputs are staggered to reduce the overall noise level on the pulse width modulation circuits. If you load the same value to the PWM0–PWM6 data registers, a match condition (data register value is equal to the 8-bit count value) will occur on the same clock cycle for all the seven 8-bit PWM circuits.

For example, the PWM0 output is delayed by one-half of a counter clock, PWM1 output by one-half of a counter clock, PWM2 output by one-half of a counter clock, and so on for the subsequent clock cycles (see Figure 15-4).

NOTE: The S3C8647 microcontroller includes just six 8-bit PWM circuits, PWM0–PWM5.

SAMSUNG
ELECTRONICS
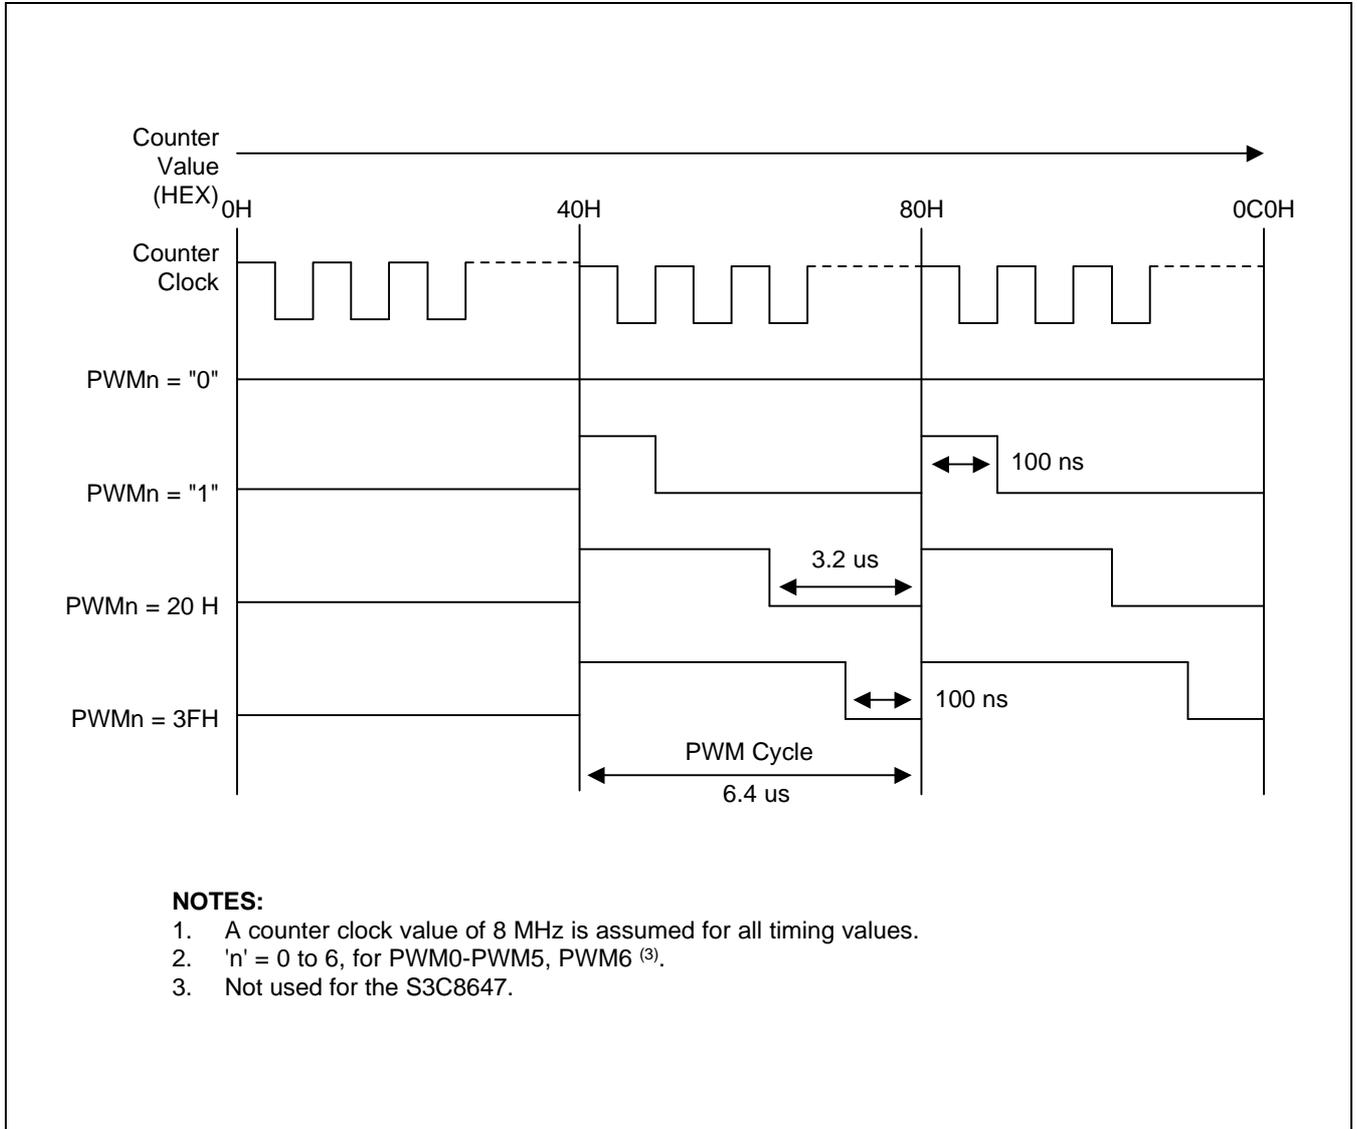

Figure 15-3. PWM Waveforms for PWM0–PWM6
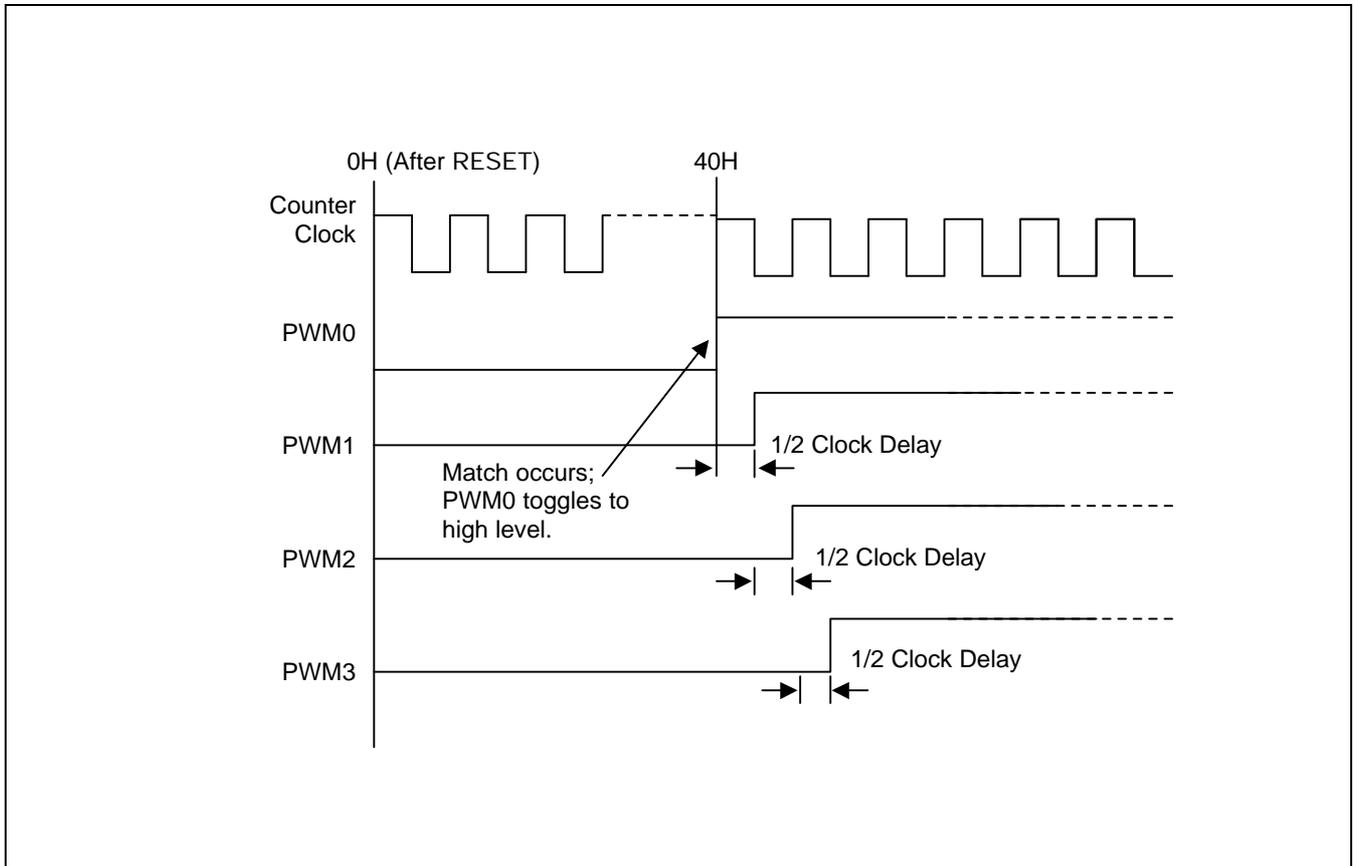

Figure 15-4. PWM Clock to PWM0–PWM6 Output Delays

PWM COUNTER

The PWM counter is an 8-bit incrementing counter. The same 8-bit counter is used by all PWM circuits. To determine the PWM module's base operating frequency, the counter is compared to the PWM data register value.

PWM DATA REGISTERS

A reset operation disables all PWM output. The current counter value is retained when the counter stops. When the counter starts, counting resumes from the retained value.

PWM CLOCK RATE

The timing of the 8-bit output channel is based on the maximum 12 MHz CPU clock frequency. The 2-bit prescaler value in the PWMCON register determines the frequency of the counter clock. You can set PWMCON.6 and PWMCON.7 to divide the CPU clock frequency by one (non-divided), two, three, or four.

As the maximum CPU clock rate for the S3C8639/C863A/C8647 microcontrollers is 12 MHz, the maximum base PWM frequency is 187.5 kHz (12 MHz divided by 64). This assumes a non-divided CPU clock.

☞ **PROGRAMMING TIP — Programming PWM0 to Sample Specifications**

This sample program executes a test of the PWM block. The program parameters are as follows:

— The oscillation frequency of the main crystal is 8 MHz

— PWM frequency is 125 kHz

SAMSUNG
ELECTRONICS

16 SYNC PROCESSOR

OVERVIEW

The S3C8639/C863A/C8647 multi-sync signal processor (sync processor) is designed to process horizontal (Hsync) and vertical (Vsync) signals that are input to a multi-sync monitor. The sync processor can perform the following functions:

— Detect sync input signals (Vsync-I, Hsync-I, and Csync-I, also called Screen-On-Green, or SOG)

— Output a programmable pseudo sync generation signal

— Detect the polarity of sync input signals

— Separate and output sync signals (Hsync-O, Vsync-O, and Clamp-O)

The sync processor circuits are controlled by three control registers: SYNCON0, SYNCON1, and SYNCON2.

Vsync SEPARATION

SYNCON0 register setting controls the output path of the sync processor's 5-bit counter. Using the 5-bit counter, the sync processor can separate the Vsync signal from composite (H+V) sync signal.

The counter value increments when a High level sync signal is detected and decrements when a Low level signal is detected. No overflow or underflow can occur. That is, the 5-bit counter increments until it reaches the maximum value of 11111B and then stops or decrements until it reaches the minimum value of 00000B. You can select fOSC/2 or fOSC/3 as the counter's clock input source.

When SYNCON0.5 is "1", a High signal level is output to a multiplexer whenever the counter value reaches 11111B and a Low level is output when the counter value reaches 00000B. The signal level remains constant when the counter value is less than 11111B or greater than 00000B.

CLAMP SIGNAL OUTPUT

SYNCON1 register settings control Clamp signal output and pulse width. Clamp output can be completely inhibited, or it can be generated at two, four, or eight times fOSC. You can specify the signal edge on which the selected Clamp pulse width is to be output ("front porch" or "back porch"). When SYNCON1.7–.6 is set to "00", the clamp signal output is inhibited. In this case the clamp signal level (Clamp-O) can be either "low" (when SYNCON1.4 is set to "1") or "high" (when SYNCON1.4 is "0").

Logic for Detecting Sync-On-Green (SOG)

Special logic in the sync processor block can compare Hsync and Csync input signals to detect Sync-On-Green (SOG). The interrupt SOG through Csync-I port is detected automatically at the SOG detection block. You can confirm to SOG by means of reading SYNCON2.2 (SOG detection bit).

Pseudo Sync Generator

SYNCON2 settings (SYNCON2.4 = "0") control the pseudo Hsync and Vsync generation registers value (See figure 16.1 and 16.2). The polarity of these frequencies is always positive, with pulse width of 2us (eight fsync clock, when fsync is 4 MHz) and 6 x PHGEN periods, respectively. The pseudo sync generator supports factory testing of the sync processor block and also protects a system against the effect of unexpected signals in transition period while mode changing.

Pseudo Hsync Generation Register (PHGEN)

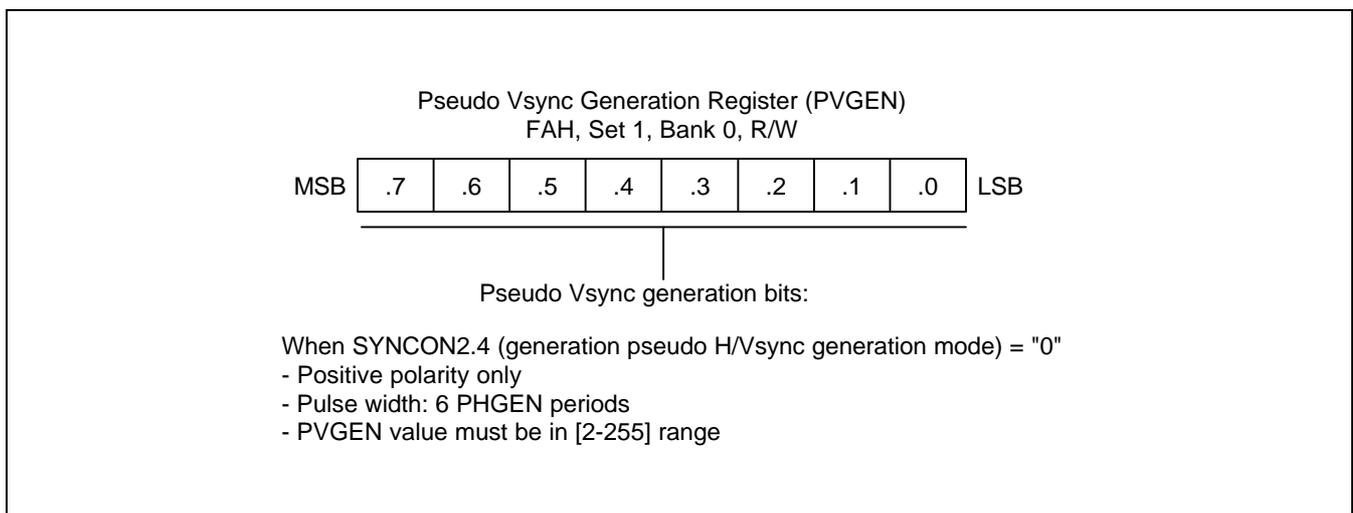

Figure 16-2. Pseudo Vsync Generation Register (PVGEN)

SAMSUNG
ELECTRONICS

Hsync & Vsync Polarity Detection, Unmixed Hsync Detection and Hsync Blanking

The polarity of Hsync & Vsync signal input to Hsync-I & Vsync-I pin is automatically detected. If the Hsync polarity is negative, SYNCON1.0 equals to "0". If the Hsync polarity is positive, SYNCON1.0 equals to "1". This polarity detection bit (SYNCON1.0) may be not accurate when the sync level is not in a transitional condition.

And if the Vsync polarity is negative, SYNCON1.1 equals to "1". This polarity detection bit (SYNCON1.1) may be not accurate when the sync level is not in a transitional condition.

In composite sync mode, if SYNCON2.7 is set to "1", the current period of checked Hsync is stable, unmixed with Vsync signal. If SYNCON2.7 is "0", the current period of checked Hsync is mixed with Vsync signal, in which case it is recommended not to calculate the sync frequency. In this mode, the Hsync signal is automatically blanked during the Vsync signal extraction period.

NOTE: Pseudo Hsync frequency = fsync/PHGEN value

Pseudo Vsync frequency = Pseudo Hsync frequency/($8 \times$ PVGEN value)

SYNC PROCESSOR CONTROL REGISTER 0 (SYNCON0)

The sync processor control register 0, SYNCON0, is located in set 1, bank 0, at address EDH. It is read/write addressable. SYNCON0 bits 4–0 hold the 5-bit counter value which is used for compare function. Whenever a High signal level is detected, the count value is incremented by one until it reaches the maximum value of "11111B" (No overflow occurs). Whenever a Low signal level is detected, the count value is decremented by one until it reaches the minimum value of "00000B" (No underflow occurs).

NOTE

When the composit sync is inputted, compare mode is also called Vsync separation mode. In this mode, output to the multiplexer is enabled. When the counter value is "11111B", the output is High level; when the counter value is "00000B", the output is Low level. Whenever the counter value is less than (<) "11111B", or greater than (>) "00000B", the previous output level is retained.

SYNCON0 settings also control the following sync processor functions:

— Horizontal or composite sync input (Hsync-I or Csync-I) selection

— Automatically enable Hsync blanking or Hsync signal bypass

— Vsync port input or 5-bit counter compare mode

— Select the clock source for Vsync-O

See Figure 16-3 for a detailed description of SYNCON0 register settings.
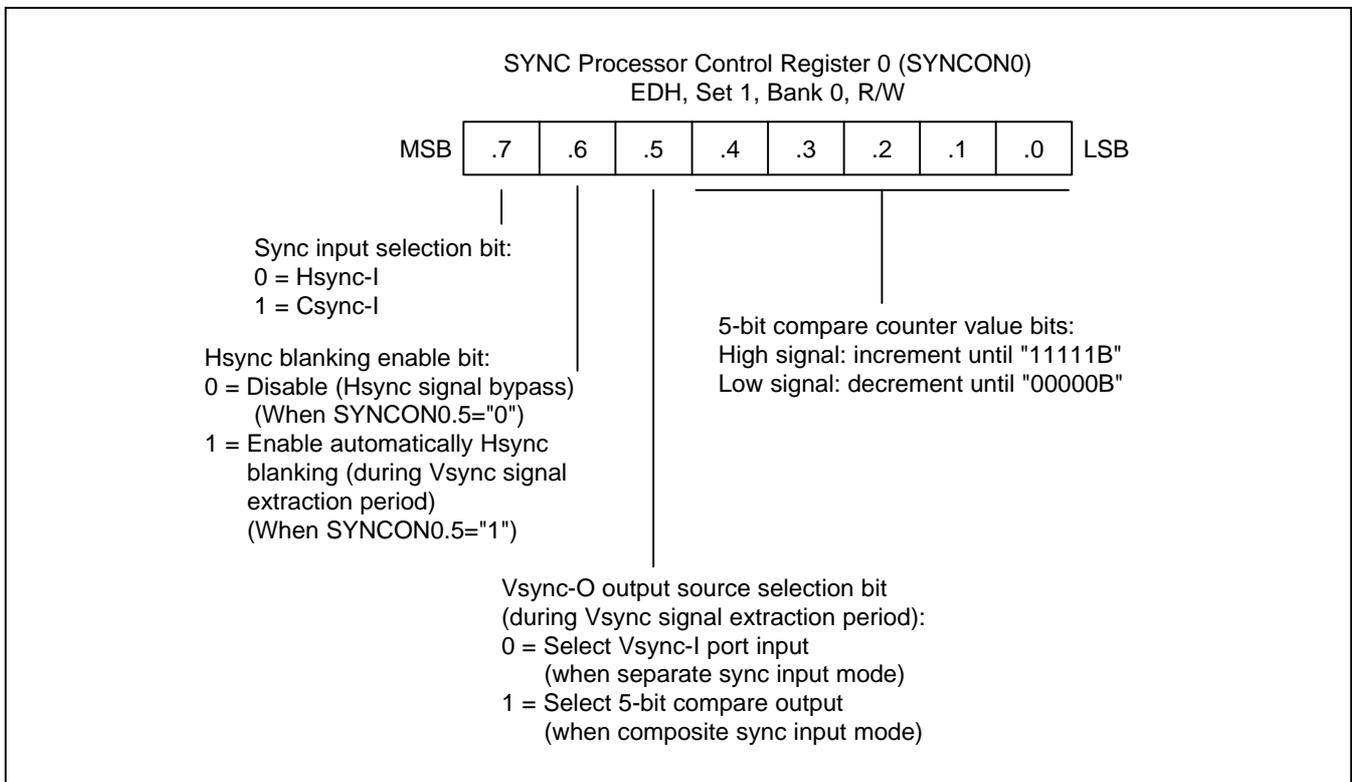

Figure 16-3. Sync Processor Control Register 0 (SYNCON0)

SYNC PROCESSOR CONTROL REGISTER 1 (SYNCON1)

The sync processor control register 1, SYNCON1, is located in set 1, bank 0, at address EEH. It is read/write addressable. Using SYNCON1 settings, you can:

— Generate a clock pulse for Clamp signal output

— Select "front porch" or "back porch" mode for Clamp-O

— Control Clamp-O, Vsync-O, and Hsync-O status

— Detect Hsync & Vsync polarity

See Figure 16-3 for a detailed description of SYNCON1 register settings.

SYNC Processor Control Register 1 (SYNCON1)
EEH, Set 1, Bank 0, R/W

Clamp output signal generation bits (CSG1,0):
00 = Inhibit clamp signal output
01 = (fosc x 2) clock pulse
    (250 ns at 8 MHz fosc)
10 = (fosc x 4) clock pulse
    (500 ns at 8 MHz fosc,
     333 ns at 12 MHz fosc)
11 = (fOSC x 8) clock pulse
    (1 us at 8 MHz,
    666 ns at 12 MHz)

Front/back porch clamp-O mode selection bit:
0 = Output clamp signal after rising
    edge of Hsync-I (front porch)
1 = Output clamp signal after falling
    edge of Hsync-I (back porch)

Hsync polarity detection bit: [2]
0 = Negative
1 = Positive

Vsync polarity detection bit: [1]
0 = Negative
1 = Positive

Hsync ouput status bit:
0 = Do not invert (by pass)
1 = Invert Hsync-O signal

Vsync ouput status bit:
0 = Do not invert (by pass)
1 = Invert Vsync-O signal

Clamp signal ouput status bit:
0 = Negative polarity
1 = Positive polarity

NOTES:
1. To check Hsync/Vsync polarity, it uses 16 clocks of timer M2 (fx/1000). If the Vsync polarity is changing, this bit will be updated after a typical delay of 2 ms, at 8 MHz fosc (1.33 ms at 12 MHz fosc)
2. The SYNCON1.0 may not be accurate when the Hsync-I is composite sync signal input.

Figure 16-4. Sync Processor Control Register 1 (SYNCON1)

SYNC PROCESSOR CONTROL REGISTER 2 (SYNCON2)

The sync processor control register 2, SYNCON2, is located in set 1, bank 0, at address EFH. It is read/write addressable. Using SYNCON2 settings, you can:

— Detect mixed and unmixed Hsync period in composite sync

— Select the pseudo sync generation enable mode

— Select the clock source for the 5-bit counter

— Sync signal output disable or enable

— SOG signal detection

— 5-bit up/down counter latch status changing detection

— V_{DD} level selection for TTL sync input ports

See Figure 16-5 for a detailed description of SYNCON2 register settings.

SYNC Processor Control Register 2 (SYNCON2)
EFH, Set 1, Bank 0, R/W

MSB .7 .6 .5 .4 .3 .2 .1 .0 LSB

Unmixed Hsync detection bit
(when SYNCON0.5 is "1", read only)
0 = Mixed Hsync period with
    Vsync of composite sync
    input [1]
1 = Unmixed Hsync periods

Not used for KS88C6332/C6348 (only "0")

5-bit counter source clock (fsync) input
selection bit:
0 = fosc/3 (when fosc is 12 MHz)
1 = fosc/2 (when fosc is 8 MHz)
* Countable maximum Hsync pulse width:
  7.85 us (when fsync is 4 MHz)

Pseudo sync generation disable bit:
0 = Enable pseudo Hsync/Vsync generation
    (positive polarity only)
1 = Normal sync-processor operation (by pass)

V_{DD} level selection bit for
TTL sync input ports (only S3C863X)
0 = When V_{DD} is +5 V
1 = When V_{DD} is +3 V

5-bit up/down counter latch status
changing detection bit:[2]
0 = When the latch status is not
    changed or it writes "0" to this bit
1 = When the latch status changing is
    detected

SOG detection bit:
0 = No SOG signal (when read)
0 = Clear SOG detection 5-bit
    counter (when write)
1 = Csync-I is SOG signal (to check SOG
    presence, it uses 64 Csync input edge
    signal)

Sync signal output disable bit:
0 = Enable sync signal output
1 = Inhibit sync signal otput
    (output level is low)

NOTES:
1. The SYNCON2.7 is still cleared before read this bit or it has been in mixed Hsync period.
2. The SYNCON2.1 can be used to check the presence of composite sync signal input

Figure 16-5. Sync Processor Control Register 2 (SYNCON2)
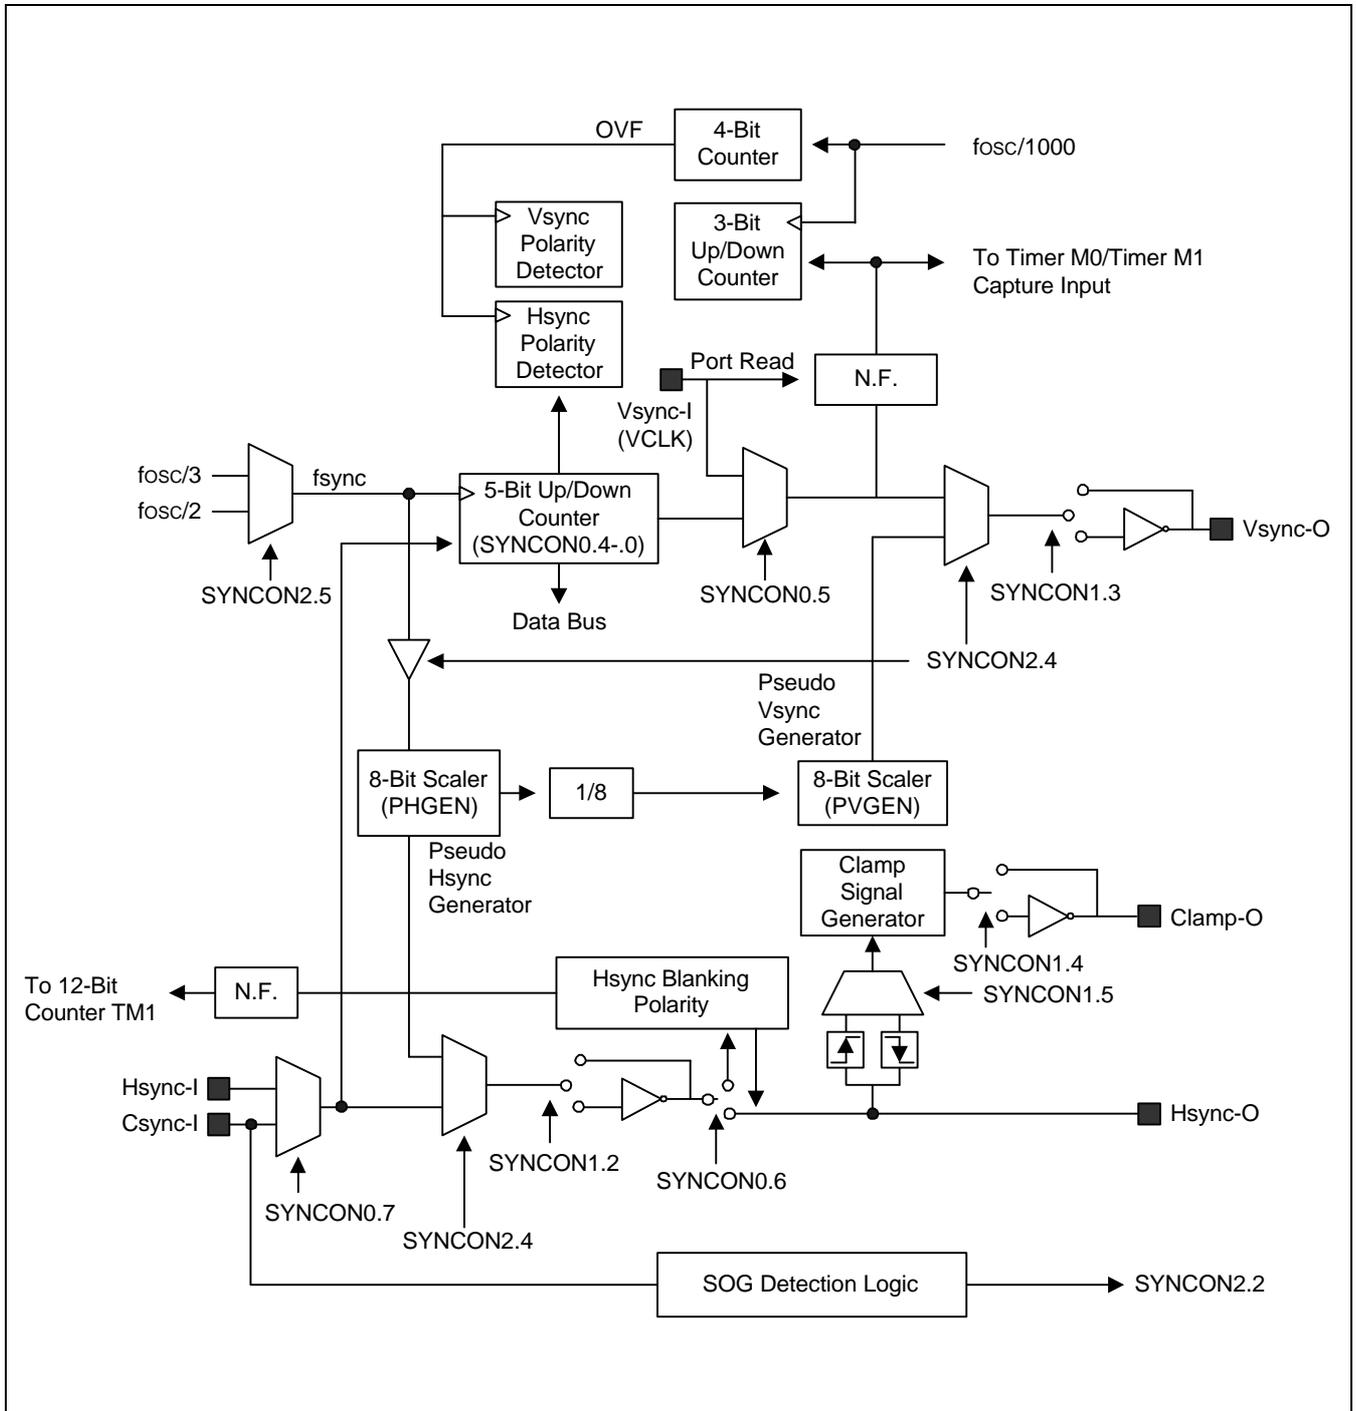

Figure 16-6. Sync Processor Block Diagram

DETECTING SYNC SIGNAL INPUT

You can detect the presence of a sync signal in two ways — directly or indirectly. The direct detection method can be implemented in read port. The indirect detection method is interrupt-driven and uses the S3C8639/C863A/C8647 sync processor hardware. These methods are explained in detail below.

Direct Detection Method

By reading the input status directly on the sync input pins Vsync-I, Hsync-I, Csync-I, you can detect the presence of the incoming sync for a corresponding output.

To enable direct sync input detection, you set SYNCON0.5 to "0" (for Vsync-I), SYNCON0.7 to "0" (for Hsync-I), and SYNCON0.7 to "1" (for Csync-I).

You then read the state of the input pin(s) over a period of time to detect transitions in the signal level(s). If a transition is detected, it can be assumed that a sync signal is present.

Indirect Detection Method

To indirectly detect vertical sync input at the Vsync-I pin, you use register settings to assign either the timer M0 capture interrupt to this pin.

For indirect detection of horizontal or composite input at the Hsync-I or Csync-I pin, you use the timer 1 input clock source to generate a timer M1 capture/overflow interrupt by capture signal from timer M2 interval or Vsync-O from sync-processor, when a signal level transition occurs. Or to detect composite sync , you can confirm to presence with checking SYNCON2.1. (This bit is used to check the presence of composite sync signal input.)

When the correct settings have been made, the application software polls for the respective interrupts to determine the presence of sync input signals, as follows:

— Indirect Vsync input detection

    Check for the occurrence of a timer M0 capture interrupt (IRQ0).

— Indirect Hsync input detection

    Check for the occurrence of a timer M1 capture/overflow interrupt (IRQ2).

— Indirect Csync input detection (SOG)

    Check for the occurrence of a timer M1 capture/overflow interrupt (IRQ2).

AUTO-DETECTING SYNC SIGNAL POLARITY

The S3C8639/C863A/C8647 sync processor lets you detect automatically the polarity of Vsync or Hsync signals by hardware. To check H/Vsync polarity, it uses 16 clocks of timer M2 (f_{OSC}/1000).

You can detect the polarity of Hsync signal inputted to Hsync-I port through checking SYNCON1.0 by the 5-bit counter of sync processor. If SYNCON1.0 is "1", the polarity of the inputting Hsync signal is positive. When SYNCON1.0 is "0", the polarity of Hsync signal is negative. But when the inputted sync signal to Hsync-I is composite sync signal (H+Vsync signal), the staus of SYNCON1.0 may not be accurate.

To detect the polarity of Vsync signal, it uses SYNCON1.1. If SYNCON1.1 is "1", the polarity of Vsync signal is positive. When the polarity of Vsync signal is negative, SYNCON1.1 is "0". If Vsync polarity is changing, SYNCON1.1 will be updated after a typical delay of 2ms, at 8 MHz f_{OSC} (1.33ms at 12 MHz f_{OSC}).
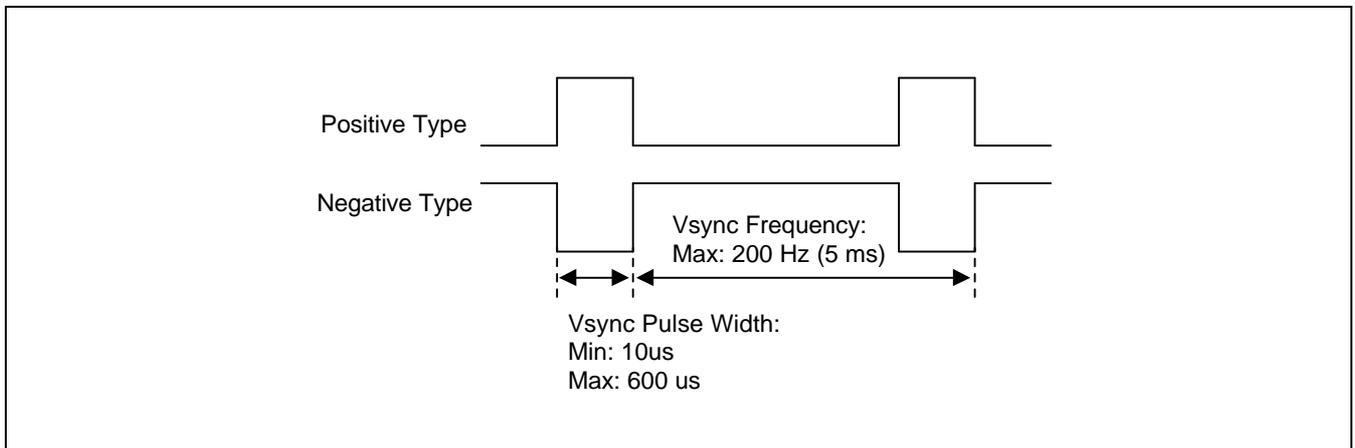

Figure 16-7. Vsync Input Timing Diagram
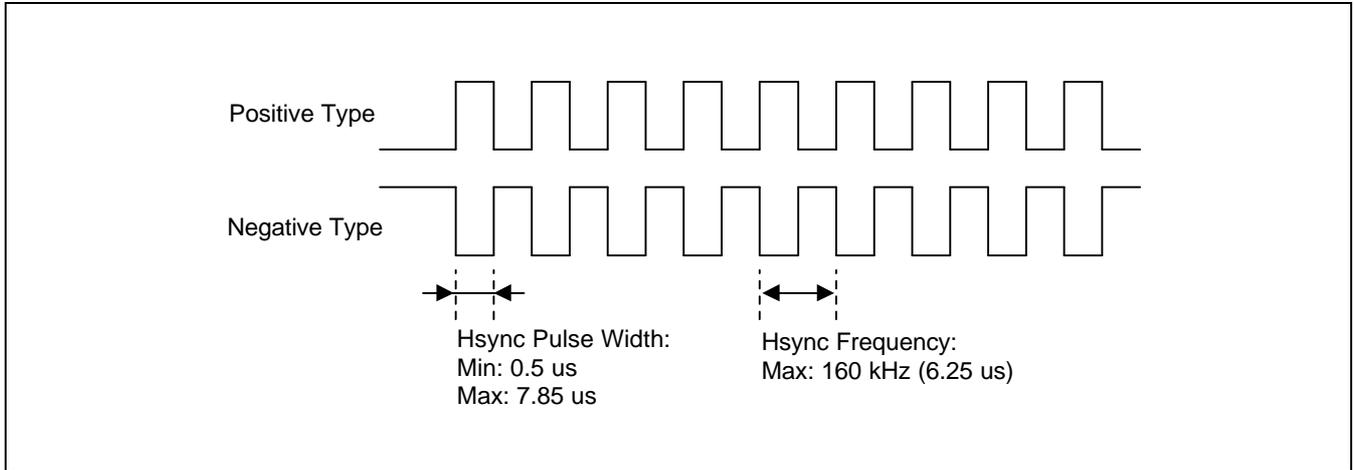

Figure 16-8. Hsync Input Timing Diagram

EXTRACTING VSYNC OUTPUT

When the Vsync input at Hsync-I or Csync-I (P2.7) also contains Hsync signals, you must extract the Vsync component from the Hsync (or Csync) input. To do this, you use the 5-bit up/down counter.

To extract the Vsync component of the input signal, you first set the 5-bit up/down counter to operate in compare mode (SYNCON0.5 = "1"). Vsync output is enabled only when the minimum or maximum threshold value is reached.

During vertical blanking, the counter decreases until it reaches a minimum value while the Hsync-I or Csync-I signal level is negative. Or, the counter value increases until it reaches a maximum value while the Hsync-I or Csync-I signal level is positive (no overflow or borrow occurs).

The timer M1 capture interrupt (IRQ2) can be enabled to verify that the Vsync signal has been extracted successfully from the mixed input signal.
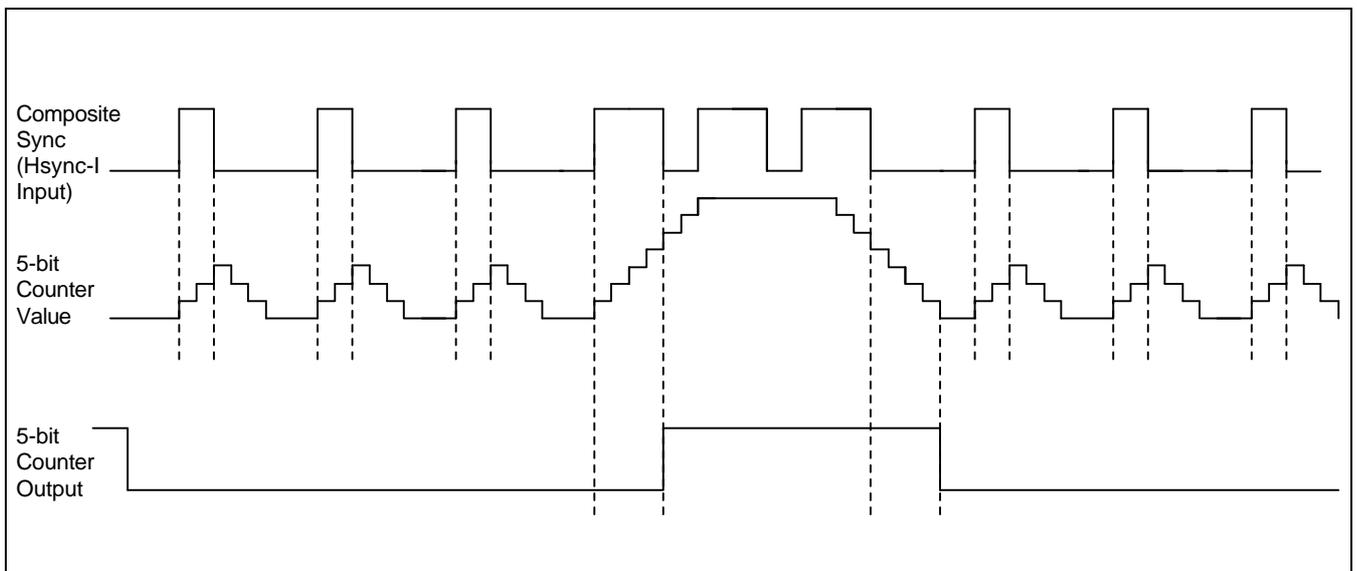

Figure 16-9. Vsync Extraction Using an Up/Down Counter

CLAMP SIGNAL OUTPUT

Clamp signal output (Clamp-O) must be synchronized with Hsync output. The Clamp-O signal can be transmitted to a vertically or horizontally driven integrated circuit to provide a pedestal level for image signals with programmable pulse width.

The Clamp signal is output on the "front porch" of an Hsync signal (NO SOG condition) or on the "back porch" of an Csync signal (SOG condition). You can control the polarity of clamp output signal with using SYNCON1.4. If you want to the negative pulse of clamp signal, you must set SYNCON1.4 to "0". If you set SYNCON1.4 to "1", the polarity of clamp output signal is positive.
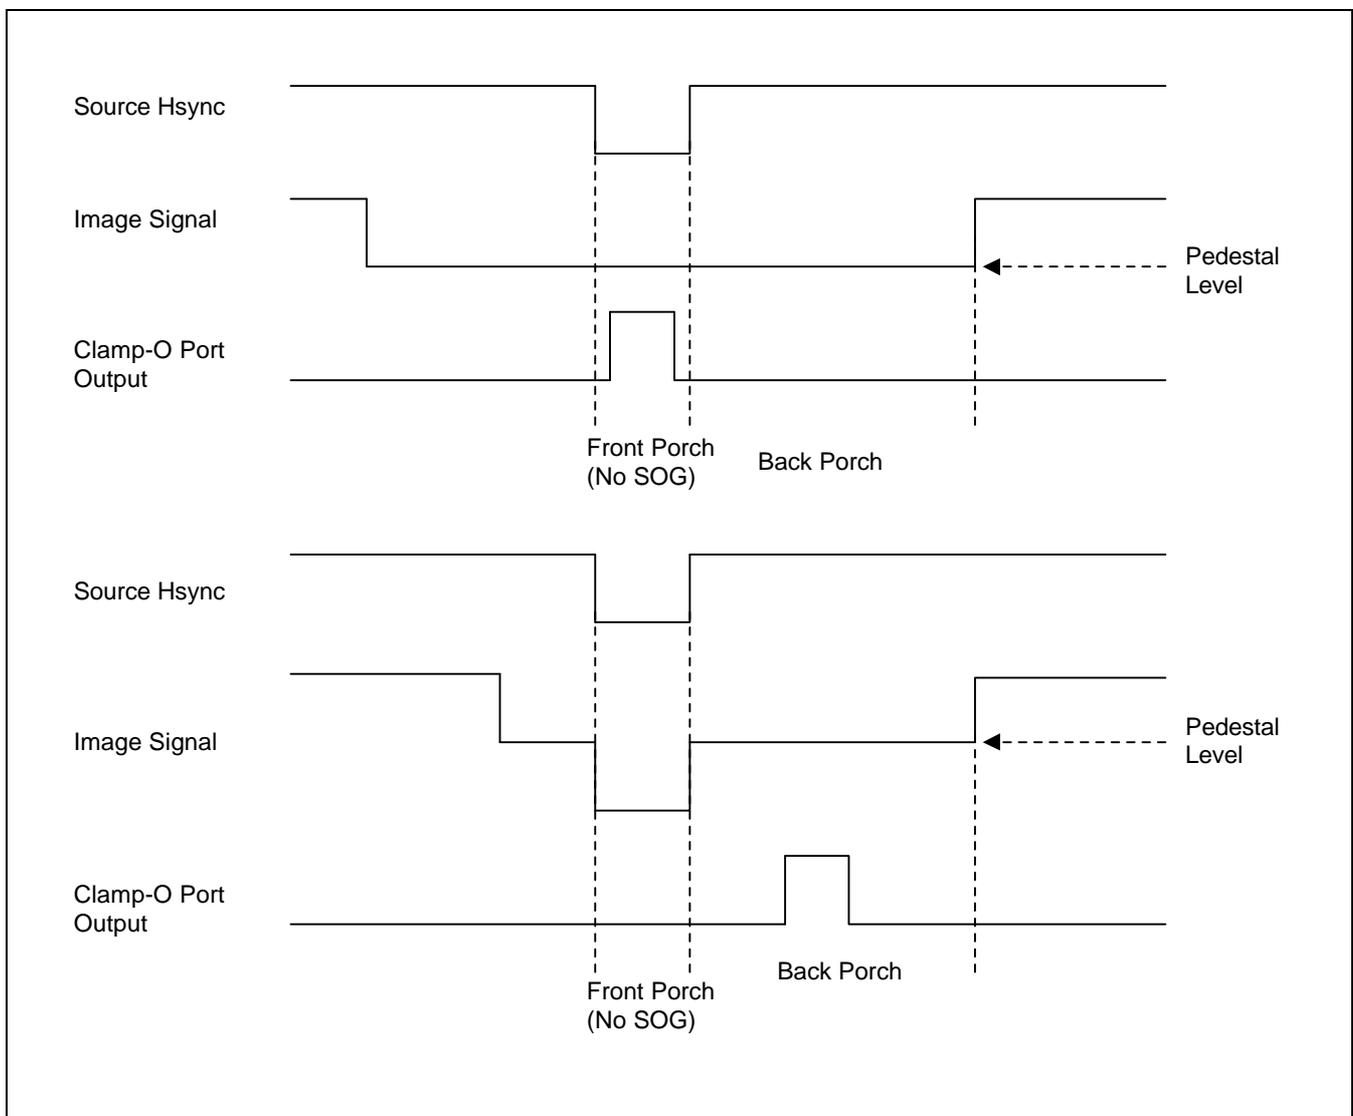

Figure 16-10. Clamp-O Signal (SOG and NO SOG Condition)

DIFFERENTIATING SOG FROM NO SOG

The pulse width at the Csync-I pin is different in SOG and NO SOG conditions. In a SOG condition, the pulse width at Csync-I and Hsync-I is identical. If a NO SOG condition exists, Csync-I has a wider pulse width than Hsync-I because the Csync-I pulse is truncated at the base of the pedestal level (see Figure 16-10).

To differentiate the Csync pulse, you must delay the Csync-I pulse for about 150 ns and then compare its phase with that of the Hsync-I pin signal.

To indicate a SOG condition, comparator logic for Hsync and Csync sets the SYNCON2.2 flag to "1" whenever Csync status differs from Hsync status more than 32 times at the rising edge of Hsync-I. To perform the comparison, first detect the polarity of the Hsync-I signal. Then configure the pin for positive output. (Csync-I is always positive and requires no special settings.) To recognize the SOG condition, you can poll the SYNCON2.2 status flag to detect when it is set to "1".

☞   **PROGRAMMING TIP — Programming the Sync Processor**

This example shows how to program the sync processor to sample specifications. The sample program performs
the following actions:

— Confirm the presence of sync signal input

— Detect the polarity of Hsync or Vsync signal input

NOTES

17 DDC MODULE

OVERVIEW

The S3C8639/C863A/C8647 microcontroller supports the DDC (Display Data Channel) interface. A pair of serial data (SDA0) and serial clock (SCL0) line (except DDC1 mode) is provided to carry information between the master and peripheral that are connected to the bus. The SDA0 and SCL0 lines are bi-directional. The DDC1 mode uses vertical sync input at the Vsync-I or VCLK (VCLK is input-only). DDC1 is implemented physically using VCLK input and SDA0 output.

Protocols for the DDC2B, DDC2Bi, and DDC2B+ are supported in hardware by multi-master IIC-bus logic and in software by the EDID (Extended Display Identification) and VDIF (Video Display Interface) formats.

To control DDC interface, you write values to the following registers:

— DDC Control Register, DCON
— DDC Clock Control Register, DCCR
— DDC Control/Status Registers 0,1, DCSR0,1
— DDC Data Shift Register, DDSR
— DDC Address Registers 0,1, DAR0,1
— Transmit Pre-buffer Data Register, TBDR
— Receive Pre-buffer Data Register, RBDR

DDC CONTROL REGISTER (DCON)

The programmable DCON register to control the DDC is located at E9H in set 1, bank 1. It is read/write addressable. Only four bits are mapped in this register.

The DCON.0 setting lets you detect falling edges at the serial clock, SCL0. If the DCON.0 is set to "0", the SCL0 (serial clock) is still high after reset (when read), or the bit can be cleared by S/W written "0" (when write). If the DCON.1 is set to "1", falling edge is detected at SCL0 pin after RESET or after this bit is cleared by S/W.

NOTE

When the DDC interrupt is occurred, SCL0 line is not pull-down at the following cases:

— DDC1 mode

— Tx/Rx pre-buffer data registers 'enable' bit, DCON.3 is "1" (only slave mode).

The DCON.1 setting lets you select normal IIC-bus interface mode or DDC1 transmit mode. If you select normal IIC-bus interface mode (DCON.1 = "0"), SCL0 pin is selected for clock line and the SCL0 falling edge (SCLF) interrupt is disabled. Or if you select DDC1 transmit mode (DCON.1 = "1"), VCLK pin is selected for clock line and the SCLF interrupt is enable.

The DCON.2 is a DDC address match bit and read-only. When the received DDC address matches to DAR0 register, DCON.2 is "1". And when it is start, stop or reset condition, DCON.2 is "0". To enable transmit or receive pre-buffer data register, DCON.3 is used. When the transmit or receive pre-buffer data register is not used, DCON.3 is "0" (normal IIC-bus mode). DCON.3 is set by writing One to it or by reset. If DCON.3 is "1", the transmit or receive pre-buffer data register is enable.

DDC Control Register (DCON)
E9H, Set 1, Bank 1, R/W (Bit 2 is read-only)

MSB | - | - | - | - | .3 | .2 | .1 | .0 | LSB

Not used for the
S3C8639/C863A/C8647

Transmit or receive pre-buffer data register
enable bit:
0 = Normal IIC-bus mode
    (Pre-buffer data registers are not used)
1 = Pre-buffer data registers enable mode
    (This bit is set by writing one to it or by
    reset)

DDC address match bit (read-only):
0 = When start or stop or reset
1 = When the received DDC address
    matches to DAR0 register

SCL0 (Serial Clock) falling
edge detection bit (SCLF):
0 = SCL0 is high after
    RESET (when read)
0 = Cleared by S/W written
    "0" (when write)
1 = Falling edge is detected
    (when read)
1 = No effect (when write)

DDC1 transmit mode enable bit:
0 = IIC-bus interface mode
    (SCL0 pins is also selected)
1 = DDC1 transmit mode
    (VCLK pin is also selected)

Figure 17-1. DDC Control Register (DCON)

SAMSUNG
ELECTRONICS

DDC Clock Control Register (DCCR)

The DDC clock control register, DCCR, is located at EBH in set 1, bank 1. It is read/write addressable. DCCR settings control the following functions:

— CPU acknowledge signal (ACK) enable or suppress

— DDC clock source selection (f_{OSC}/10 or f_{OSC}/256)

— DDC interrupt enable or disable

— DDC interrupt pending control

— 4-bit prescaler for the serial clock (SCL0)

When DCCR.7 bit is set to "1", it is enable to acknowledgment signal. DCCR.6 is bit for transmit clock source selection by f_{OSC}/10 or f_{OSC}/256. DCCR.3–DCCR.0 bits (CCR3–CCR0) are 4-bit prescaler for the transmit clock (SCL0). The SCL0 clock may be "Stretched" if a slow slave device holds the clock for clock synchronization.

In the S3C8639/C863A/C8647 interrupt structure, the DDC interrupt is assigned level IRQ3, vector EAH. To enable this interrupt, you set DCCR.5 to "1". Program software can then poll the DDC interrupt pending bit(DCCR.4) to detect DDC interrupt request. When the CPU acknowledges the interrupt request from the DDC, the interrupt service routine must clear the interrupt pending condition by writing a "0" to DCCR.4.

DDC Clock Control Register (DCCR)
EBH, Set 1, Bank 1, R/W

| MSB | .7 | .6 | .5 | .4 | .3 | .2 | .1 | .0 | LSB |

Transmit acknowledge (ACK)
enable bit:
0 = Disable ACK generation
1 = Enable ACK generation

Transmit clock source selection bit:
0 = fosc/10
1 = fosc/256

DDC module interrupt enable bit:
0 = Disable DDC interrupt
1 = Enable DDC interrupt

DDC module interrupt pending flag:
0 = When write "0" to this bit (write "1" has no effect)
0 = When DCSR0.4 is "0"
1 = When slave address match occurred
1 = When arbitration lost (master mode)
1 = When a 1-byte transmit or receive operation is terminated
1 = As soon as the DDC1 mode is enable after the prebuffer is used

Transmit clock 4-bit prescaler bits:

The transmit clock (SCL0) frequency is determined by the clock source selection (DCCR.6) and this 4-bit prescaler value, according to the following formula:

SCL0 clock = IICCLK/(DCCR.3-DCCR.0) + 1

where, IICCLK is fosc/10 (DCCR.6 = "0") or
IICCLK is fosc/256 (DCCR.6 = "1")

SAMSUNG
ELECTRONICS

DDC CONTROL/STATUS REGISTER 0 (DCSR0)

The DDC control/status register 0, DCSR0, is located at ECH in set 1, bank 1. It is read/write addressable. Although the DCSR0 register is read/write addressable, four bits are read only: DCSR0.3–DCSR0.0.

DCSR0 register settings are used to control or monitor the following functions:

— Master/slave transmit or receive mode selection

— Bus busy status flag

— DDC module enable or disable

— Failed bus arbitration procedure status flag

— Received address register match status flag

— Last received bit status flag (No ACK = "1", ACK = "0")

DCSR0.3 is automatically set to "1" when a bus arbitration procedure fails over serial I/O interface, while the IIC-bus is set to master mode. If slave mode is selected, DCSR0.3 is automatically set to "1" if the value of DCSR0.7–.4 are changed by program when the busy signal bit, DCSR0.5 is "1", and the DDC address/data field classification bit, DCSR0.2 is "0". When the DDC module is transmitting a One to SDA0 line but detected a Zero from SDA0 line in master mode at the slave mode, DCSR0.3 is set.
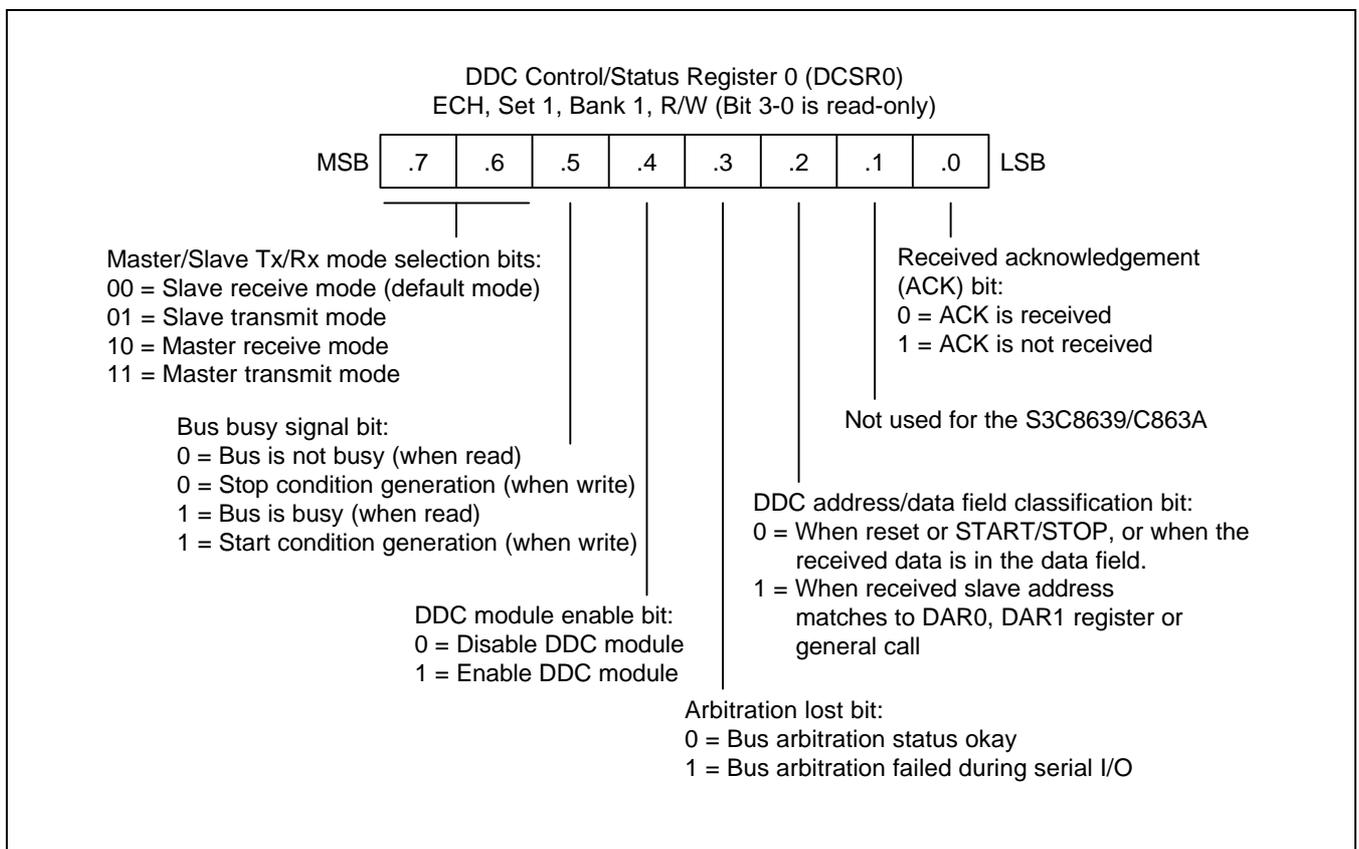

Figure 17-3. DDC Control/Status Register 0 (DCSR0)

DDC CONTROL/STATUS REGISTER 1 (DCSR1)

The DDC control/status register 1, called DCSR1, is located at EDH in set 1, bank 1. It is read/write addressable. Only three bits are mapped in this register. Two bits are read-only: DCSR1.1 and DCSR1.0.

DCSR1 register settings are used to control or monitor the following functions:

— Stop condition detection flag

— Data buffer empty status flag

— Data buffer full status flag

DDC Control/Status Register 1 (DCSR1)
EDH, Set 1, Bank 1, R/W (Bits 1 and 0 are read-only)

MSB | - | - | - | - | - | .2 | .1 | .0 | LSB

Not used for the S3C8639/C863A/C8647

Stop condition detection bit:
0 = When it writes "0" to this bit, and
    reset or master mode
1 = When a stop condition isdetected
    after START and slave address
    reception

Data buffer full status bit:
0 = When the CPU reads the
    received data from the
    RBDR register or STOP
    condition
1 = When thd data or matched
    address is transferred from
    the DDSR register to the
    RBDR register

Data buffer empty status bit:
0 = When the CPU writes the transmitting data into the
    TBDR register
1 = When the data of the TBDR register loads to the DDSR
    register or when a stop condition is detected in PCSR0.7-6
    (slave transmission mode) = "01"

Figure 17-4. DDC Control/Status Register 1 (DCSR1)

SAMSUNG
ELECTRONICS

DDC DATA SHIFT REGISTER (DDSR)

The DDC data shift register for DDC interface, called DDSR, is located at F1H in set 1, bank 1. It is read/write addressable. The transmitted data output serially from most significant bit (MSB) after writing a data to DDSR. In addition, the received data from the IIC-bus input to DDSR serially from least significant bit (LSB). DDSR register capable to write while DCSR0.4 is set to "1" and DCON.3 is set to "0", and to read anytime regardless of ICSR0.4.

DDC Data Shift Register (DDSR)
F1H, Set 1, Bank 1, R/W

MSB | .7 | .6 | .5 | .4 | .3 | .2 | .1 | .0 | LSB

8-bit data shift register for DDC Tx/Rx operations:
Write enable when DCSR0.4 is "1" and DCON.3 is
"0". Read enable anytime.
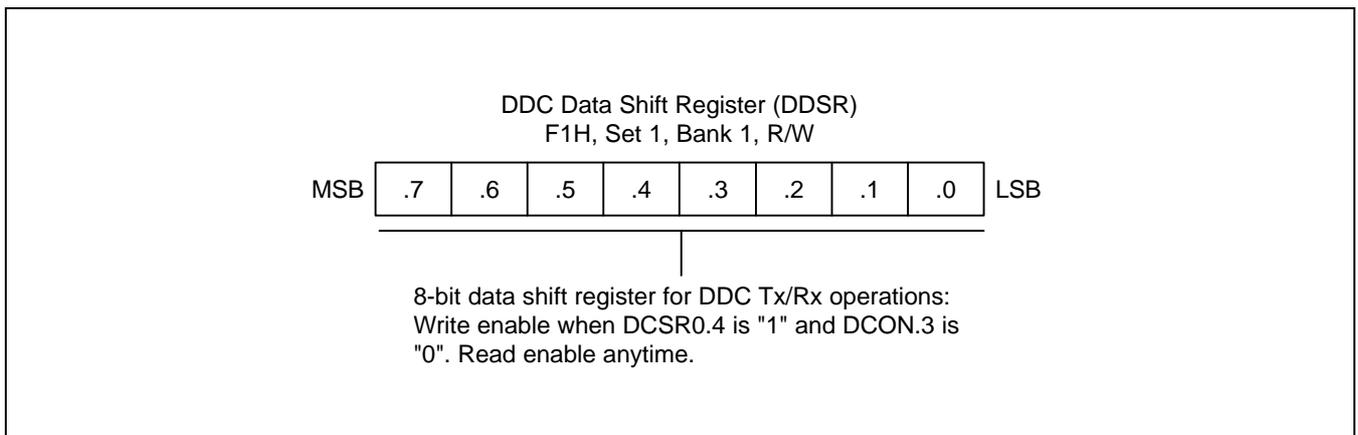

Figure 17-5. DDC Data Shift Register (DDSR)

DDC ADDRESS REGISTER 0 (DAR0)

The DDC address register 0 for DDC interface, called DAR0, is located at EAH in set 1, bank 1. It is read/write addressable. This register is consisted of 4-bit slave address latch (DAR0.3–DAR0.0 is not mapped at the S3C8639/C863A/C8647). DAR0 register is capable to write when DCSR0.4 is "0", and to read anytime regardless of DCSR0.4. 4-bits of the DAR0 register are operate only when receive the slave address.
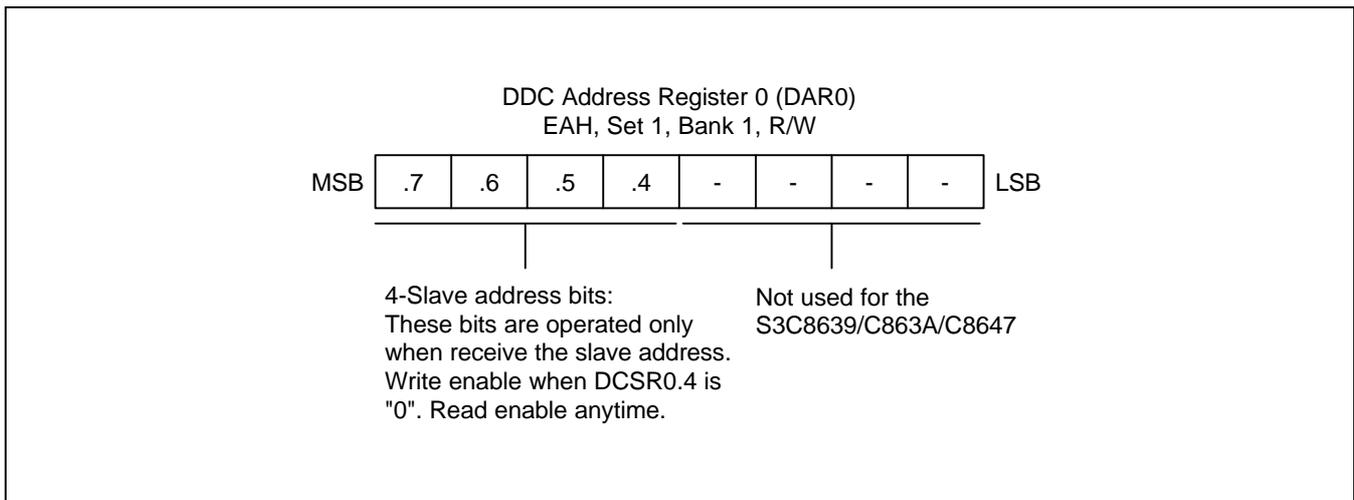

Figure 17-6. DDC Address Register 0 (DAR0)

DDC ADDRESS REGISTER 1 (DAR1)

The DDC address register 1 for DDC interface, called DAR1, is located at EEH in set 1, bank 1. It is read/write addressable. This register is consisted of 7-bit slave address latch (DAR1.0 is not mapped at the S3C8639/C863A/C8647). DAR1 register is capable to write when DCSR0.4 is "0", and to read anytime regardless of DCSR0.4. 7-bits of the DAR1 register are operate only when receive the slave address.
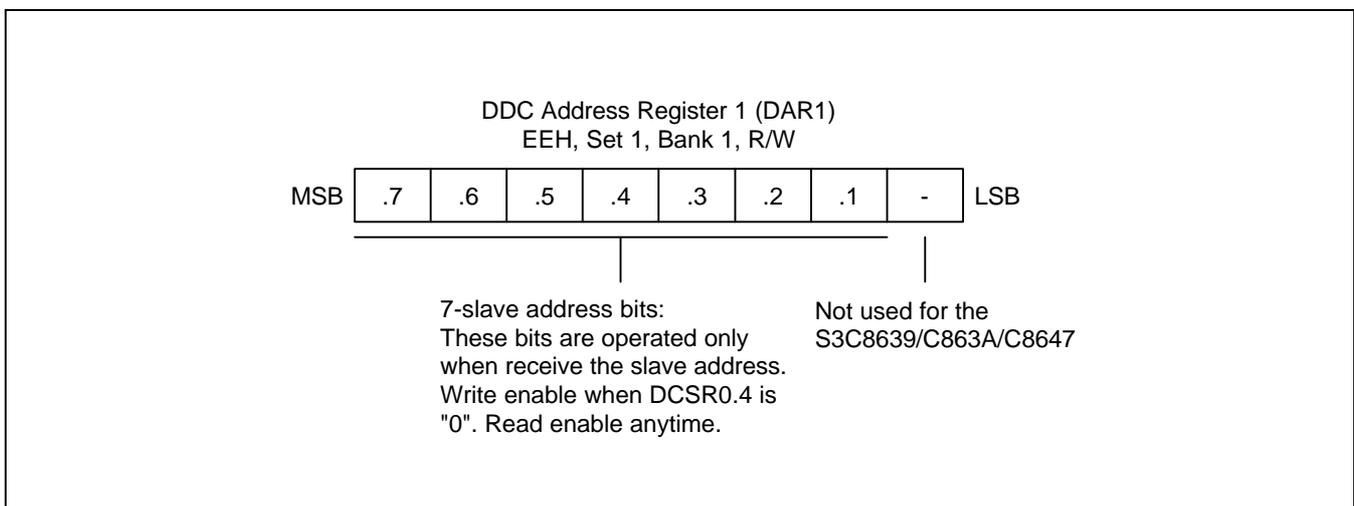

Figure 17-7. DDC Address Register 1 (DAR1)

SAMSUNG
ELECTRONICS

TRANSMIT PRE-BUFFER DATA REGISTER (TBDR)

The transmit pre-buffer data register, called TBDR, is located at EFH in set 1, bank 1. It is read/write addressable. TBDR register is capable to write when DCSR0.4 is "1", and to read anytime regardless of DCSR0.4.

When DCON.3 (TBDR enable bit) = "1" and DCSR1.1 = "0", the data written into this register will be automatically downloaded to the DDC data shift register (DDSR) and generate the interrupt request when the module detects the calling address is matched and the bit 0 of the received data is "1" (DCSR0.7-6 = "01") and when the data in the DDSR register has been transmitted with received acknowledge bit, DCSR0.0 = "0".

At this interrupt service routine, the CPU must write the next data to the TBDR register to clear DCSR1.1 and for the auto downloading of data to the DDSR register after the data in the DDSR register is transmitted over again with DCSR0.0 = "0". When DCON.3 = "1" and DCSR1.1 = "1", the data stored in this register will not be downloaded to the module detects the calling address is matched and the bit 0 of the received data is "1".

At this interrupt service routine, the CPU must write the current data and rewrite the next data to the TBDR register to clear DCSR1.1. If the master receiver doesn't acknowledge the transmitted data, DCSR0.0 = "1", the module will release the SDA line for master to generate STOP or repeated START conditions. If DCON.3 (TBDR enable bit) is "0", the module will pull-down the SCL line in the IIC-bus interrupt service routine when the DCSR0.2 is "1". And the module will release the SCL line if the CPU writes a data to the DDSR registers and the interrupt pending bit is cleared.
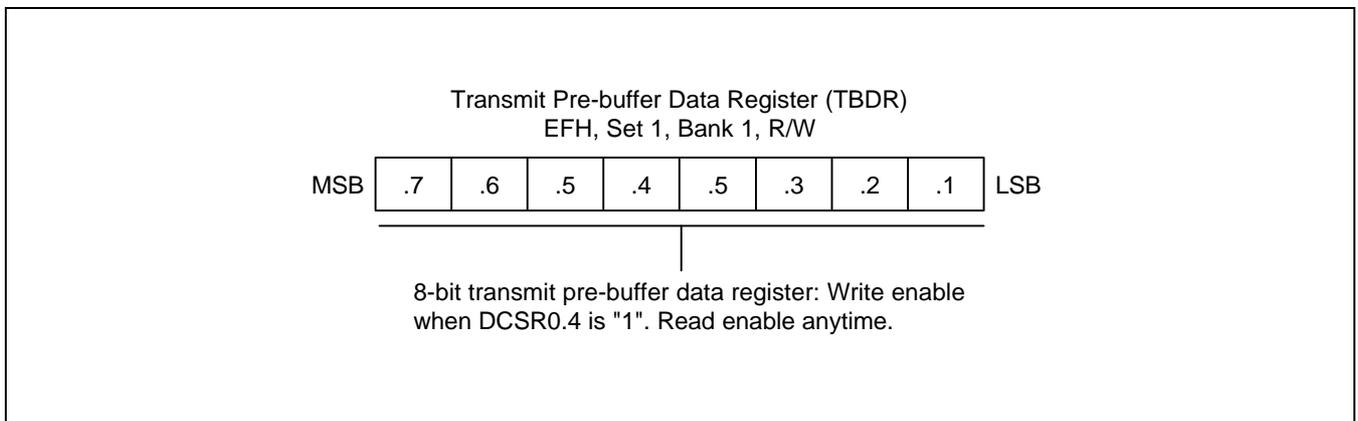

Figure 17-8. Transmit Pre-buffer Data Register (TBDR)

RECEIVE PRE-BUFFER DATA REGISTER (RBDR)

The receive pre-buffer data register, called RBDR, is located at F0H in set 1, bank 1. It is read-only addressable. RBDR register is capable to read anytime.

RBDR register will be updated after a data byte is received when the DCSR0.2 is "1"and the DCSR1.0 will be "1". The read operation of RBDR register will clear the DCSR1.0. After the DCSR1.0 is cleared, the register can load the received data again and set the DCSR1.0.

THE DDC INTERFACE

DDC2BI MODE

Overview

DDC2B capable graphic hosts have limited and mono-directional communications with the display devices. At the contrary, DDC2Bi mode is an extension of the DDC2B level in order to offer a bi-direction communication between the computer graphic host and the display device. DDC2Bi brings DDC2B+ functionality to DDC2B graphic hosts using a simple S/W driver. So DDC2Bi display device is made by simple S/W upgrade to DDC2B+ capable displays. DDC2Bi protocol relies on the DDC2B H/W definition and the Access bus messages protocol. The Graphic host behaves as an IIC single master host, and the display device behaves as an IIC slave device. The DDC2Bi is a modification of the Access bus multi-master protocol to fit single master communication.

DDC2Bi Host and Display Device

DDC2Bi host is considered as an IIC single master capable device. The virtual IIC slave address of the host is 50/51H. But DDC2Bi display device is considered as a fixed address display device (6E/6F), and uses only IIC slave mode to communicate with the host.

A display dependent devices are geographically located around the display and follow the same DDC2Bi data protocol than the display device. And fixed address IIC slave devices group all the existing stand-alone and brain-less IIC slave device. These devices can coexist and be connected to the DDC/IIC-bus.

DDC2Bi S/W Implementation

In order to describe the display that the received message is of DDC2Bi type, the source address byte bit 0 is set. And when the host expects an answer from the display, the host reads the answer message at the display device slave address 6FH. The checksum is still computed by using the 50H, virtual host address.

A null message can be defined as an Access bus message without any data byte. The null message is used in the following cases:

— To detect that the display is DDC2Bi capable by reading it at 6FH, IIC slave address.

— To describe the host that the display does not have any answer to give to the host

— The enable application report has not been sent prior application messages exchange with the host

DDC2Bi Communication

In the DDC2Bi communication, it is capable to retrials when a communication fails (bus error or bad checksum). So the host is responsible for resending its message and trying to get an answer from the display again. When the communication fail is occurred, the DDC2Bi devices must answer by the retry of host.

The DDC2Bi capable device must properly send and receive all its supported messages. This determines the maximum internal data communication buffer required size for proper display operation. If the device receive a message which size is lager than the maximum supported by the device, the message be accepted entirely by the device, but does not need to be supported internally, and then be discarded. Therefore the DDC2Bi capable device must acknowledge all received data bytes from the host.

SAMSUNG
ELECTRONICS

THE IIC-BUS INTERFACE

The S3C8639/C863A/C8647 IIC-bus interface has four operating modes:

— Master transmitter mode

— Master receive mode

— Slave transmitter mode

— Slave receive mode

Functional relationships between these operating modes are described below.

START AND STOP CONDITIONS

When the IIC-bus interface is inactive, it is in slave mode. The interface is therefore always in slave mode when a start condition is detected on the SDA line. (A start condition is a High-to-Low transition of the SDA line while the clock signal, SCL, is High level.) When the interface enters master mode, it initiates a data transfer and generates the SCL signal.

A start condition initiates a one-byte serial data transfer over the SDA line and a stop condition ends the transfer. (A stop condition is a Low-to-High transition of the SDA line while SCL is High level.) Start and stop conditions are always generated by the master. The IIC-bus is "busy" when a start condition is generated. A few clocks after a stop condition is generated, the IIC-bus is again "free".

When a master initiates a start condition, it sends its slave address onto the bus. The address byte consists of a 7-bit address and a 1-bit transfer direction indicator (that is, write or read). If bit 8 is "0", a transmit operation (write) is indicated; if bit 8 is "1", a request for data (read) is indicated.

The master ends the indicated transfer operation by transmitting a stop condition. If the master wants to continue sending data over the bus, it can the generate another start condition and another slave address. In this way, read-write operations can be performed in various formats.
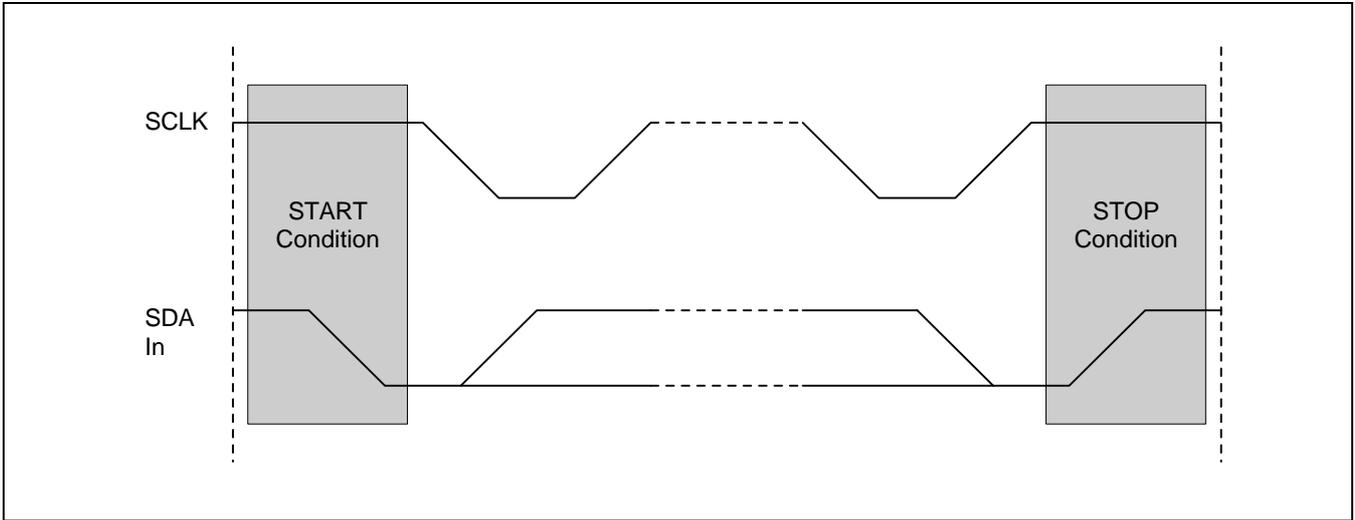

Figure 17-12. Start and Stop Conditions
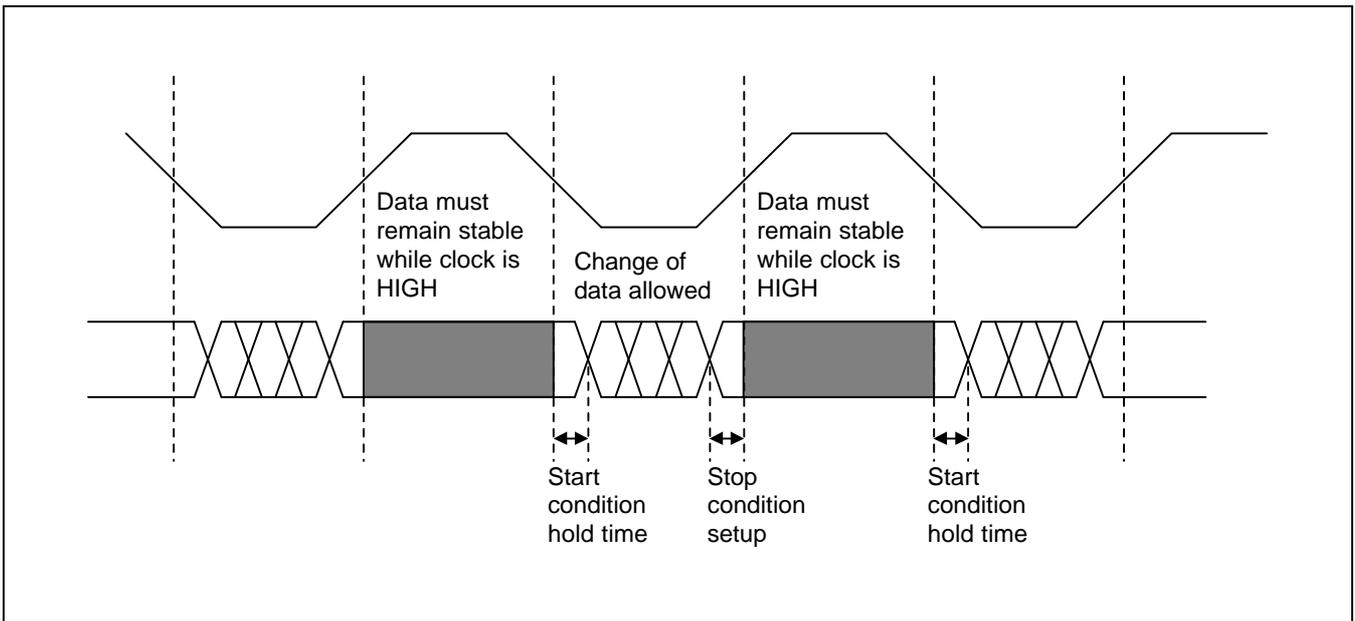

Figure 17-13. Input Data Protocol

DATA TRANSFER FORMATS

Every byte put on the SDA line must be eight bits in length. The number of bytes which can be transmitted per transfer is unlimited. The first byte following a start condition is the address byte. This address byte is transmitted by the master when the IIC-bus is operating in master mode. Each byte must be followed by an acknowledge (ACK) bit. Serial data and addresses are always sent MSB first.
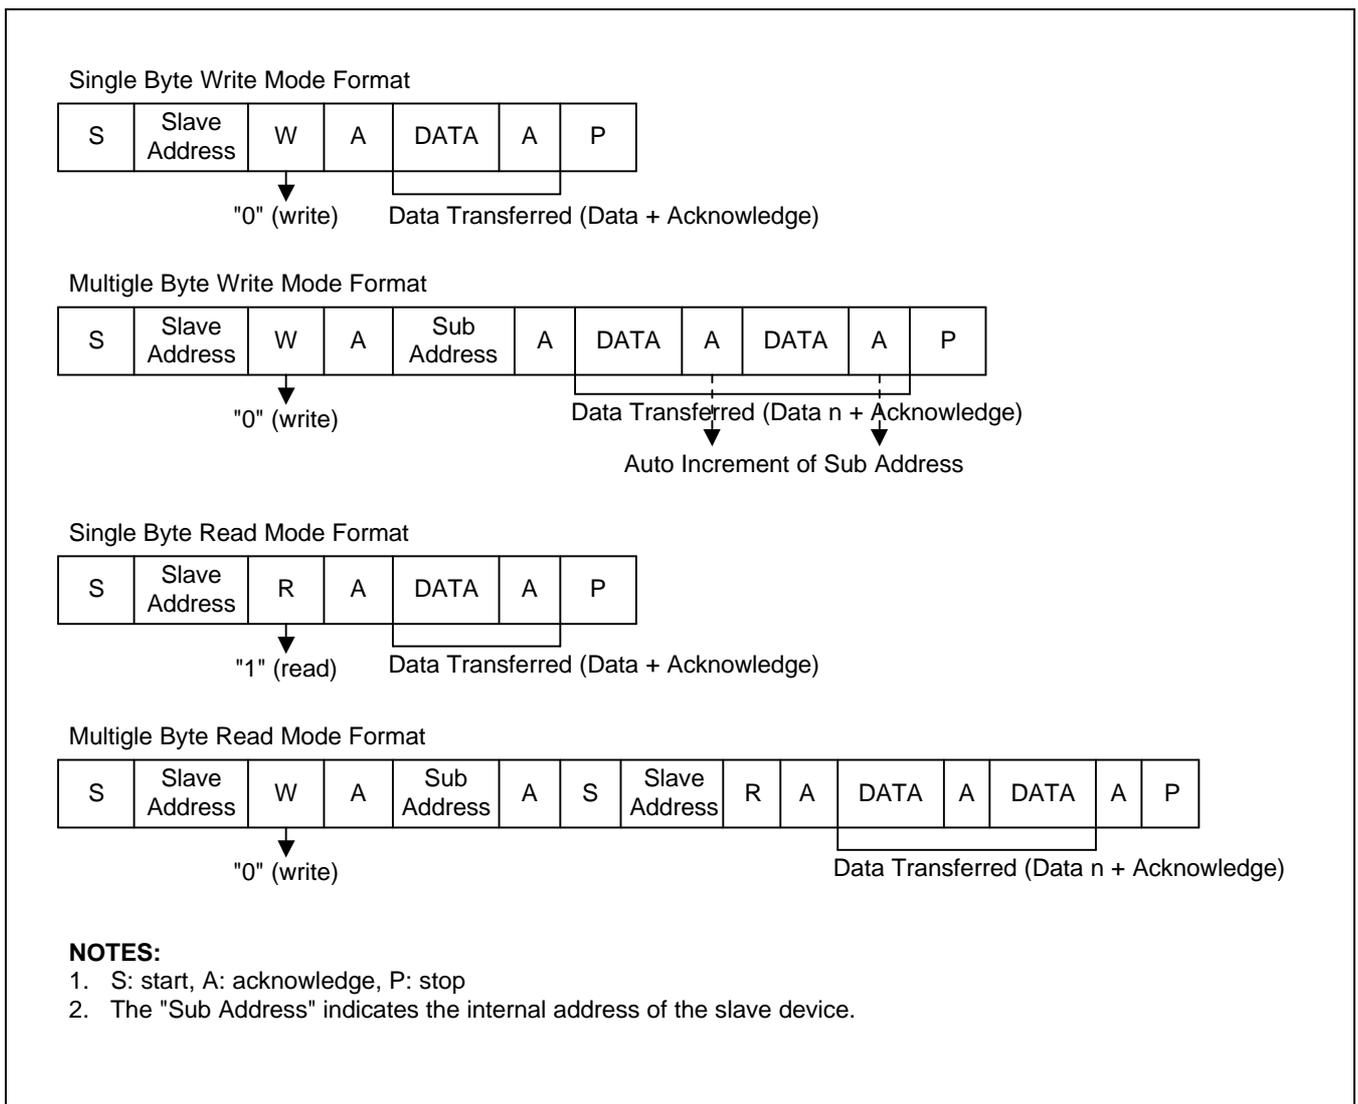

Figure 17-14. IIC-Bus Interface Data Formats

ACK SIGNAL TRANSMISSION

To complete a one-byte transfer operation, the receiver must send an ACK bit to the transmitter. The ACK pulse occurs at the ninth clock of the SCL line (eight clocks are required to complete the one-byte transfer). The clock pulse required for the transmission of the ACK bit is always generated by the master.

The transmitter releases the SDA line (that is, it sends the SDA line High) when the ACK clock pulse is received. The receiver must drive the SDA line Low during the ACK clock pulse so that SDA is Low during the High period of the ninth SCL pulse.

The ACK bit transmit function can be enabled and disabled by software (DCCR.7). However, the ACK pulse on the ninth clock of SCL is required to complete a one-byte data transfer operation.
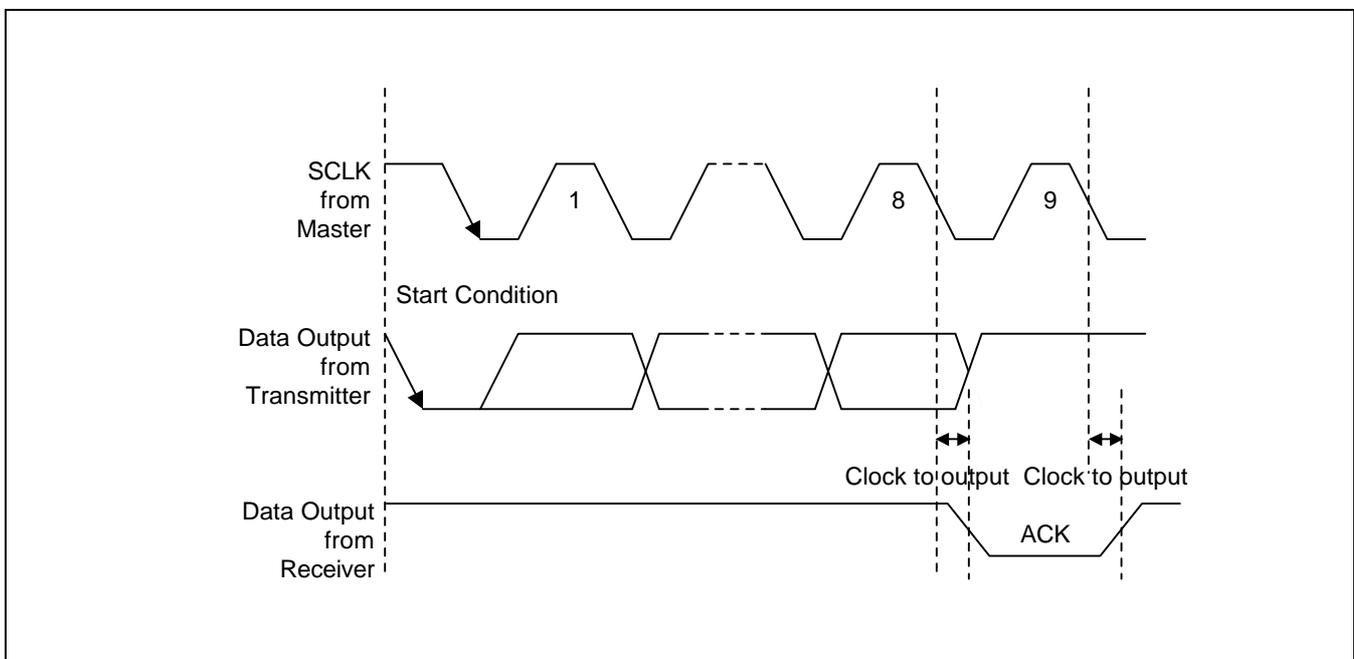

Figure 17-15. Acknowledge Response from Receiver

READ-WRITE OPERATIONS

When operating in transmitter mode, the IIC-bus interface interrupt routine waits for the master (the KS88C6332/C6348) to write a data byte into the IIC-bus data shift register (DDSR). To do this, it holds the SCL line Low prior to transmission.

In receive mode, the IIC-bus interface waits for the master to read the byte from the IIC-bus data shift register (DDSR). It does this by holding the SCL line Low following the complete reception of a data byte.

BUS ARBITRATION PROCEDURES

Arbitration takes place on the SDA line to prevent contention on the bus between two masters. If a master with a SDA High level detects another master with an SDA active Low level, it will not initiate a data transfer because the current level on the bus does not correspond to its own. The master which loses the arbitration can generate SCL pulses only until the end of the last-transmitted data byte. The arbitration procedure can continue while data continues to be transferred over the bus.

The first stage of arbitration is the comparison of address bits. If a master loses the arbitration during the addressing stage of a data transfer, it is possible that the master which won the arbitration is attempting to address the master which lost. In this case, the losing master must immediately switch to slave receiver mode.

ABORT CONDITIONS

If a slave receiver does not acknowledge the slave address, it must hold the level of the SDA line High. This signals the master to generate a stop condition and to abort the transfer.

If a master receiver is involved in the aborted transfer, it must also signal the end of the slave transmit operation. It does this by not generating an ACK after the last data byte received from the slave. The slave transmitter must then release the SDA to allow a master to generate a stop condition.

CONFIGURING THE IIC-BUS

To control the frequency of the serial clock (SCL), you program the 4-bit prescaler value in the DCCR register. The IIC-bus interface address is stored in IIC-bus address register, DIAR0/DAR1. (By default, the IIC-bus interface address is an unknown value.)

NOTES

18 SLAVE IIC-BUS INTERFACE (Only S3C863X)

OVERVIEW

The S3C8639/C863A microcontroller supports a slave only IIC-bus serial interface.

A dedicated serial data line (SDA) and a serial clock line (SCL) carry information between bus master and slave devices which are connected to the IIC-bus. The SDA is bi-directional. But in the S3C8639/C863A/C8647, the SCL line is uni-directional (input only).

S3C8639/C863A microcontroller can receive and transmit serial data to and from master. When the IIC-bus is free, the SDA and SCL lines are both at high level.

To control slave-only IIC-bus operations, you write values to the following registers:

— Slave only IIC-bus control/status register, SICSR

— Slave only IIC-bus Tx/Rx data shift register, SIDSR

— Slave only IIC-bus address register, SIAR

Start and Stop conditions are always generated by the master. A 7-bit address value in the first data byte that is put onto the bus after the Start condition is initiated determines which slave device the bus master selects. The 8th bit determines the direction of the transfer (read or write).

Every data byte that is put onto the SDA line must total eight bits. The number of bytes which can be sent or received per bus transfer operation is unlimited.

Refer to the IIC-bus interface (slave Tx/Rx) of chapter 17 for the protocol of the slave IIC-bus at the S3C8639/C863A.

SLAVE ONLY IIC-BUS CONTROL/STATUS REGISTER (SICSR)

The slave only IIC-bus control/status register, SICSR, is located in set 1, bank 1, at address F2H. SICSR register settings are used to control or monitor the following slave IIC-bus functions (see figure 18-4):

— Slave IIC-bus acknowledgement (ACK) signal generation enable or suppress

— Slave IIC-bus module enable

— Slave IIC-bus Tx/Rx interrupt enable

— Slave IIC-bus Tx/Rx interrupt pending condition control

— Slave IIC-bus Tx/Rx mode status detect/control

— Slave IIC-bus busy status detect

— Slave IIC-bus address match status detect

— Received acknowledge signal detect (No ACK = "1", ACK = "0")
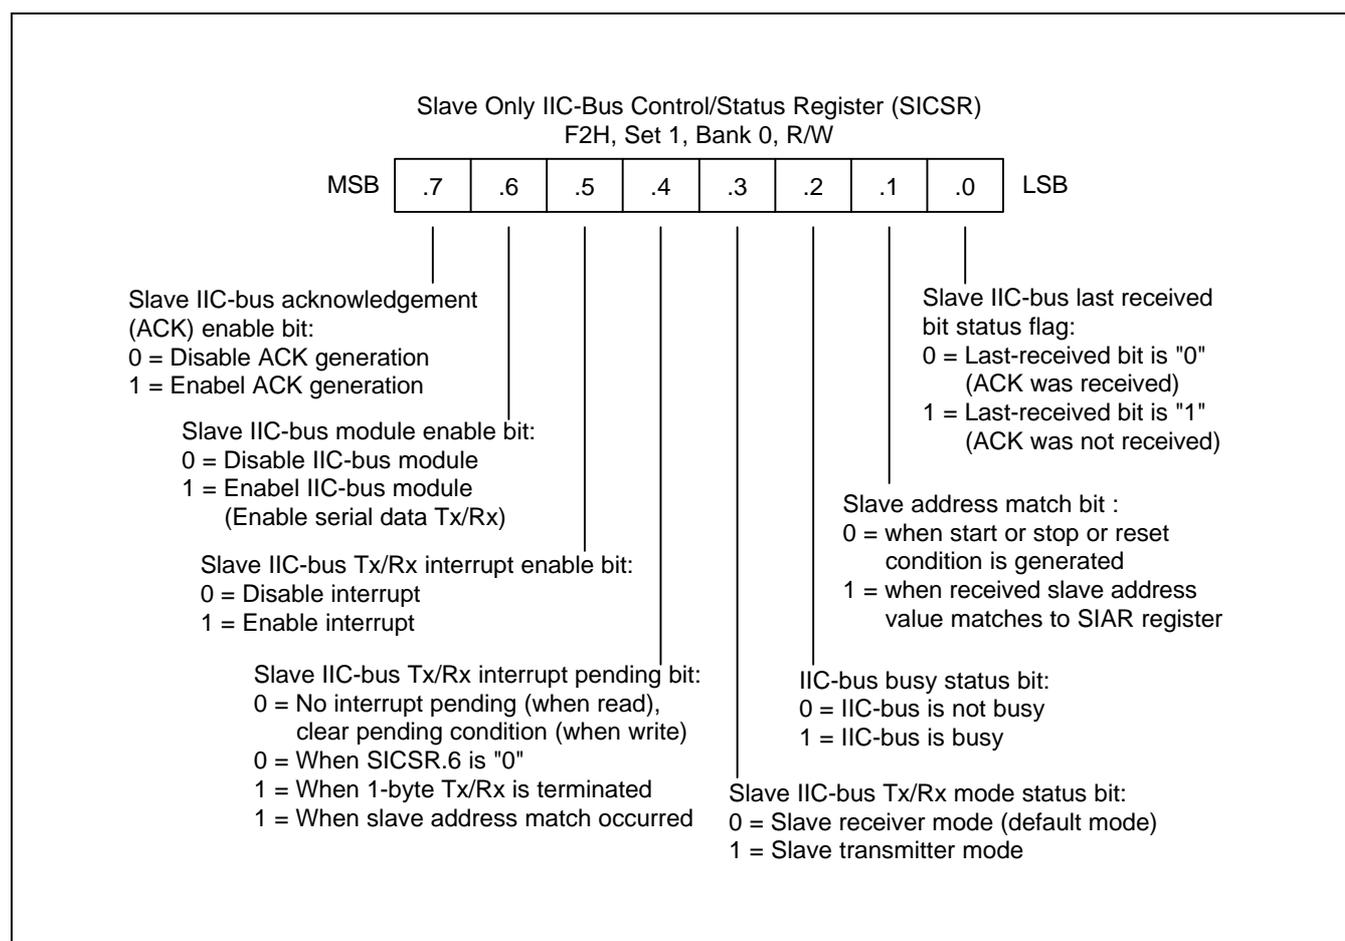

Figure 18-1. Slave only IIC-Bus Control/Status Register (SICSR)

SLAVE ONLY IIC-BUS TRANSMIT/RECEIVE DATA SHIFT REGISTER (SIDSR)

The slave IIC-bus data shift register, SIDSR, is located in set 1, bank 1, at address F4H. In a transmit operation, data that is written to the IIC is transmitted serially.

The SICSR.6 setting enables or disables serial transmit/receive operations. When SICSR.6 = "1", data can be written to the shift register. The slave IIC-bus shift register can, however, be read at any time, regardless of the current SICSR.6 setting.

19 ELECTRICAL DATA

OVERVIEW

In this section, S3C8639/C863A/C8647 electrical characteristics are presented in tables and graphs. The information is arranged in the following order:

— Absolute maximum ratings

— D.C. electrical characteristics

— Data retention supply voltage in stop mode

— Stop mode release timing when initiated by a reset

— I/O capacitance

— A/D Converter electrical characteristics

— A.C. electrical characteristics

— Input timing measurement points for P0.0–P0.2 and TM0CAP

— Oscillation characteristics

— Oscillation stabilization time

— Clock timing measurement points for X_{IN}

— Schmitt trigger characteristics

— Power-on reset circuit characteristics

Table 19-1. Absolute Maximum Ratings

$(T_A = 25°C)$

Parameter	Symbol	Conditions	Rating	Unit
Supply voltage	V_{DD}	–	-0.3 to $+6.5$	V
Input voltage	V_{I1}	Type G-3 (n-channel open drain)	-0.3 to $+7.0$	
	V_{I2}	All port pins except V_{I1}	-0.3 to $V_{DD} + 0.3$	
Output voltage	V_O	All output pins	-0.3 to $V_{DD} + 0.3$	
Output current High	I_{OH}	One I/O pin active	-10	mA
		All I/O pins active	-60	
Output current Low	I_{OL}	One I/O pin active	$+30$	
		Total pin current except port 3	$+100$	
		Sync-processor I/O pins and IIC-bus clock and data pins	$+150$	
Operating temperature	T_A	–	-40 to $+85$	°C
Storage temperature	T_{STG}	–	-65 to $+150$

Table 19-5. A/D Converter Electrical Characteristics (S3C863X)

$(T_A = -40 \,°C \; to \; +85 \,°C, \; V_{DD} = 3.0 \, V \; to \; 5.5 \, V, \; V_{SS} = 0 \, V)$

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Resolution			–	8	–	bit
Total accuracy		V_{DD} = 5 V Conversion time = 5 μs	–	–	± 2	LSB
Integral linearity error	ILE	AV_{REF} = 5 V		–	± 1	
Differential linearity error	DLE	AV_{SS} = 0 V		–	± 1	
Offset error of top	EOT			± 1	± 2	
Offset error of bottom	EOB			± 0.5	± 2	
Conversion time [1]	t_{CON}	8-bit conversion 48 x n/f_{OSC} [3], n = 1, 4, 8, 16	20	–	170	μs
Analog input voltage	V_{IAN}	–	AV_{SS}	–	AV_{REF}	V
Analog input impedance	R_{AN}	–	2	1000	–	MΩ
Analog reference voltage	AV_{REF}	–	2.5	–	V_{DD}	V
Analog ground	AV_{SS}	–	V_{SS}	–	V_{SS} + 0.3	V
Analog input current	I_{ADIN}	AV_{REF} = V_{DD} = 5V	–	–	10	μA
Analog block Current [2]	I_{ADC}	AV_{REF} = V_{DD} = 5V	–	1	3	mA
		AV_{REF} = V_{DD} = 3V		0.5	1.5	mA
		AV_{REF} = V_{DD} = 5V When power down mode		100	500	nA

NOTES:
1. "Conversion time" is the time required from the moment a conversion operation starts until it ends.
2. I_{ADC} is an operating current during the A/D conversion.
3. f_{OSC} is the main oscillator clock.

Table 19-6. A/D Converter Electrical Characteristics (S3C8647)

($T_A = -40°C$ to $+85°C$, V_{DD} = 4.0 V to 5.5 V, V_{SS} = 0 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Resolution	–		–	4	–	bit
Absolute accuracy [1]	–	4 bit conversion $24 \times n/f_{OSC}$ [3], n = 1, 4, 8, 16	–	–	± 0.5	LSB
Conversion time [2]	t_{CON}		3	–	–	us
Analog input voltage	V_{IAN}	–	V_{SS}	–	V_{DD}	V
Analog input impedance	R_{AN}	–	2	–	–	$M\Omega$

NOTES:

1. Excluding quantization error, absolute accuracy values are within ± 0.5 LSB.
2. "Conversion time" is the time required from the moment a conversion operation starts until it ends.
3. f_{OSC} is the mean oscillator clock.

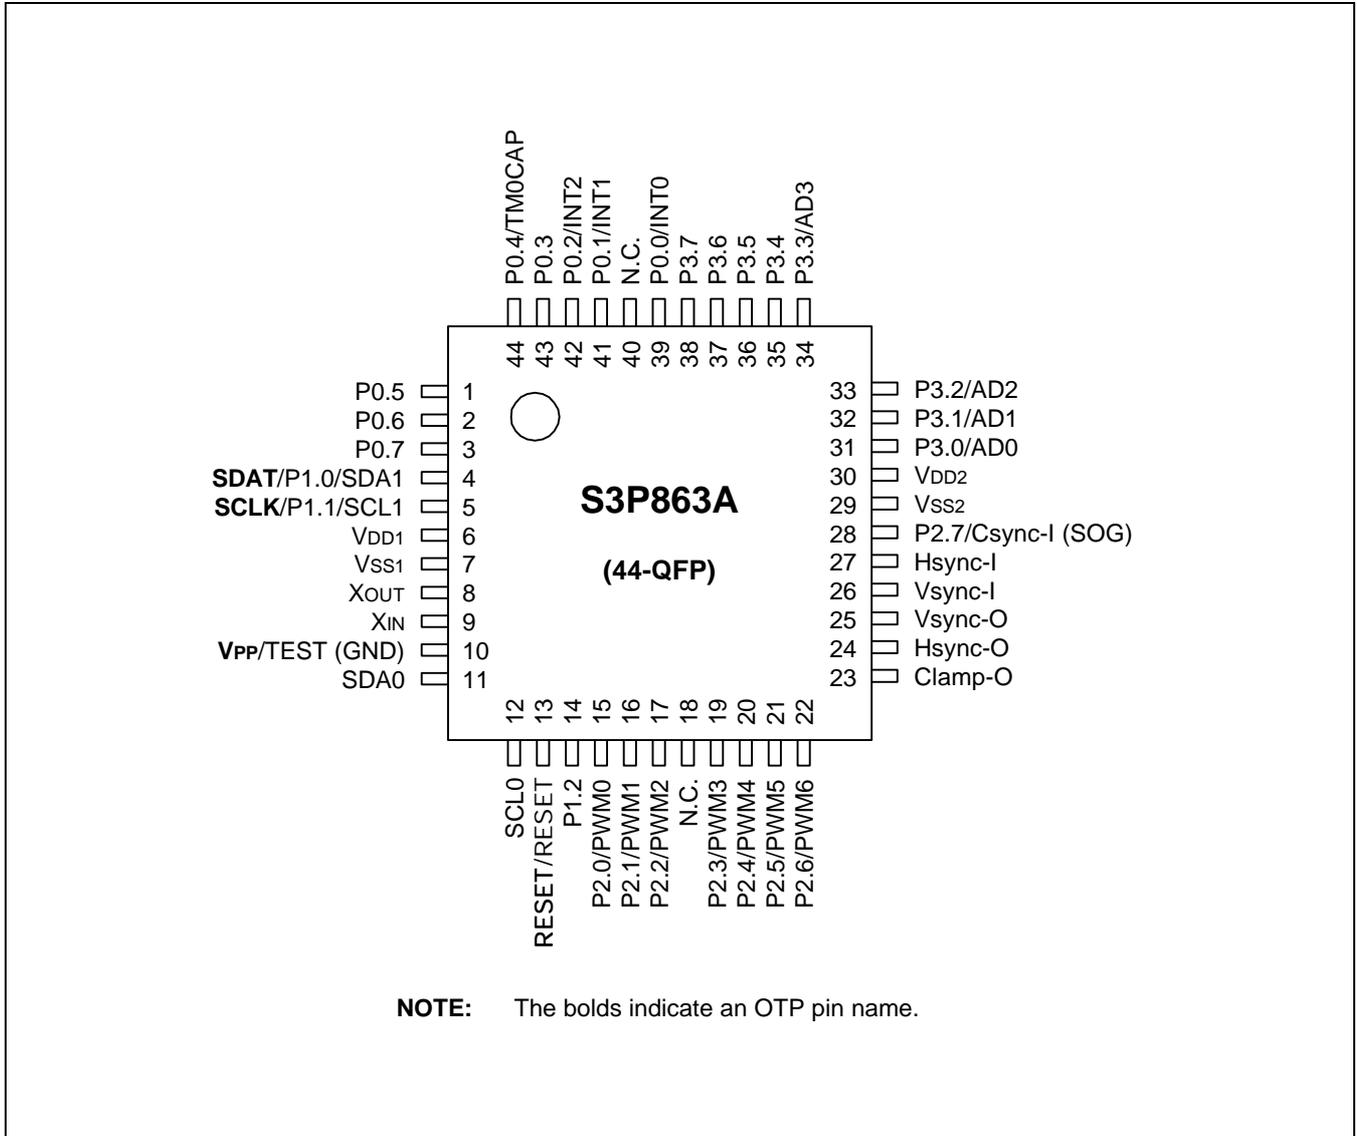

Figure 21-2. S3P863A Pin Assignments (44-QFP Package)

Table 21-1. Descriptions of Pins Used to Read/Write the EPROM

Main Chip	During Programming			
Pin Name	Pin Name	Pin Number	I/O	Function
P1.0	SDAT	9 (4)	I/O	Serial data pin. Output port when reading and input port when writing. Can be assigned as a Input/push-pull output port.
P1.1	SCLK	10 (5)	I	Serial clock pin. Input only pin.
TEST	V_{PP} (TEST)	15 (10)	I	Power supply pin for EPROM cell writing (indicates that OTP enters into the writing mode). When 12.5 V is applied, OTP is in writing mode and when 5 V is applied, OTP is in reading mode. (Option)
RESET	RESET	18 (13)	I	Chip Initialization
V_{DD1}/V_{SS1}	V_{DD1}/V_{SS1}	11/12 (6/7)	I	Logic power supply pin. V_{DD} should be tied to +5 V during programming.

NOTE: Parentheses indicate 44-QFP OTP pin number.

Table 21-2. Comparison of S3P863A and S3C8639/C863A Features

Characteristic	S3P863A	S3C8639/C863A
Program Memory	48-Kbyte EPROM	32/48-Kbyte mask ROM
Operating Voltage (V_{DD})	3.0 V to 5.5 V	3.0 V to 5.5V
OTP Programming Mode	V_{DD} = 5 V, V_{PP} (TEST) = 12.5V	
Pin Configuration	42 SDIP, 44 QFP	42 SDIP, 44 QFP
EPROM Programmability	User Program 1 time	Programmed at the factory

OPERATING MODE CHARACTERISTICS

When 12.5 V is supplied to the V_{PP}(TEST) pin of the S3P863A, the EPROM programming mode is entered. The operating mode (read, write, or read protection) is selected according to the input signals to the pins listed in Table 21-3 below.

Table 21-3. Operating Mode Selection Criteria

V_{DD}	V_{PP} (TEST)	REG/MEM	Address (A15–A0)	R/W	Mode
5 V	5 V	0	0000H	1	EPROM read
	12.5 V	0	0000H	0	EPROM program
	12.5 V	0	0000H	1	EPROM verify
	12.5 V	1	0E3FH	0	EPROM read protection

NOTE: "0" means Low level; "1" means High level.

D.C. ELECTRICAL CHARACTERISTICS

Table 21-4. D.C. Electrical Characteristics

$(T_A = -40\,°C \text{ to } +85\,°C, V_{DD} = 3.0\,V \text{ to } 5.5\,V)$

Parameter	Symbol	Conditions	Min	Typ	Max	Unit

NOTE: Supply current does not include drawn internal pull-up/pull-down resistors and external loads of output.

SAMSUNG
ELECTRONICS

NOTES

23 DEVELOPMENT TOOLS

OVERVIEW

Samsung provides a powerful and easy-to-use development support system in turnkey form. The development support system is configured with a host system, debugging tools, and support software. For the host system, any standard computer that operates with MS-DOS as its operating system can be used. One type of debugging tool including hardware and software is provided: the sophisticated and powerful in-circuit emulator, SMDS2+, for S3C7, S3C9, S3C8 families of microcontrollers. The SMDS2+ is a new and improved version of SMDS2. Samsung also offers support software that includes debugger, assembler, and a program for setting options.

SHINE

Samsung Host Interface for In-Circuit Emulator, SHINE, is a multi-window based debugger for SMDS2+. SHINE provides pull-down and pop-up menus, mouse support, function/hot keys, and context-sensitive hyper-linked help. It has an advanced, multiple-windowed user interface that emphasizes ease of use. Each window can be sized, moved, scrolled, highlighted, added, or removed completely.

SAMA ASSEMBLER

The Samsung Arrangeable Microcontroller (SAM) Assembler, SAMA, is a universal assembler, and generates object code in standard hexadecimal format. Assembled program code includes the object code that is used for ROM data and required SMDS program control data. To assemble programs, SAMA requires a source file and an auxiliary definition (DEF) file with device specific information.

SASM88

The SASM88 is an relocatable assembler for Samsung's S3C8-series microcontrollers. The SASM88 takes a source file containing assembly language statements and translates into a corresponding source code, object code and comments. The SASM88 supports macros and conditional assembly. It runs on the MS-DOS operating system. It produces the relocatable object code only, so the user should link object file. Object files can be linked with other object files and loaded into memory.

HEX2ROM

HEX2ROM file generates ROM code from HEX file which has been produced by assembler. ROM code must be needed to fabricate a microcontroller which has a mask ROM. When generating the ROM code (.OBJ file) by HEX2ROM, the value "FF" is filled into the unused ROM area upto the maximum ROM size of the target device automatically.

TARGET BOARDS

Target boards are available for all S3C8-series microcontrollers. All required target system cables and adapters are included with the device-specific target board.

OTPs

One time programmable microcontroller (OTP) for the S3C8639/C863A microcontroller and OTP programmer (Gang) are now available.

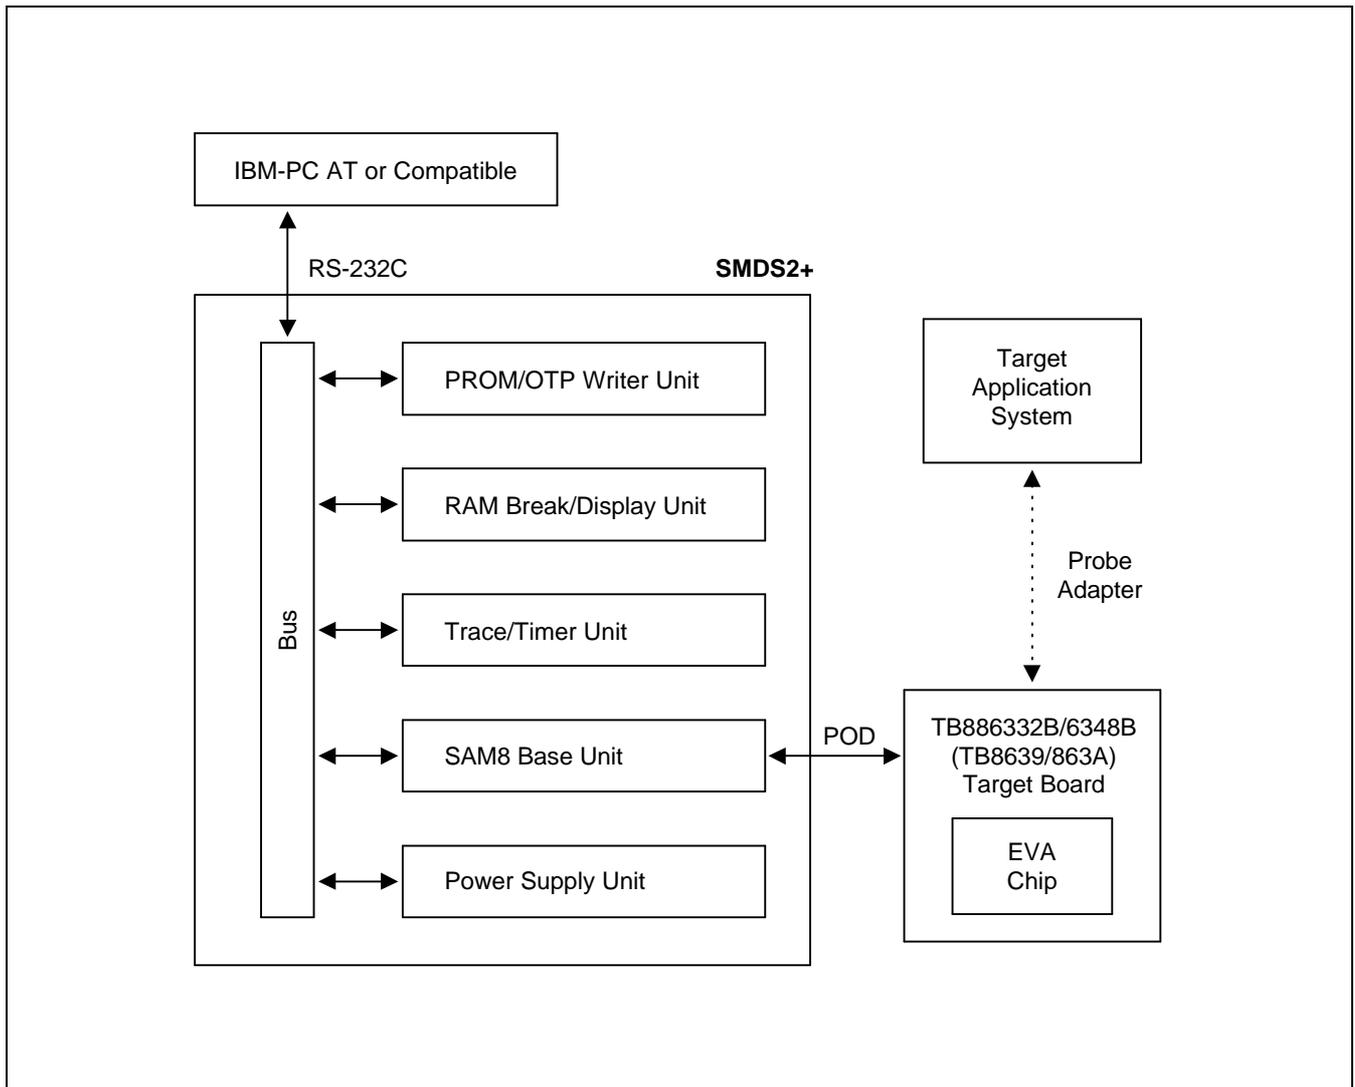

Figure 23-1. SMDS Product Configuration (SMDS2+)

SAMSUNG
ELECTRONICS

TB886332B/6348B (TB8639/863A) TARGET BOARD

The TB886332B/6348B (TB8639/863A) target board is used for the S3C8639/C863A microcontroller. It is supported by the SMDS2+ development system.

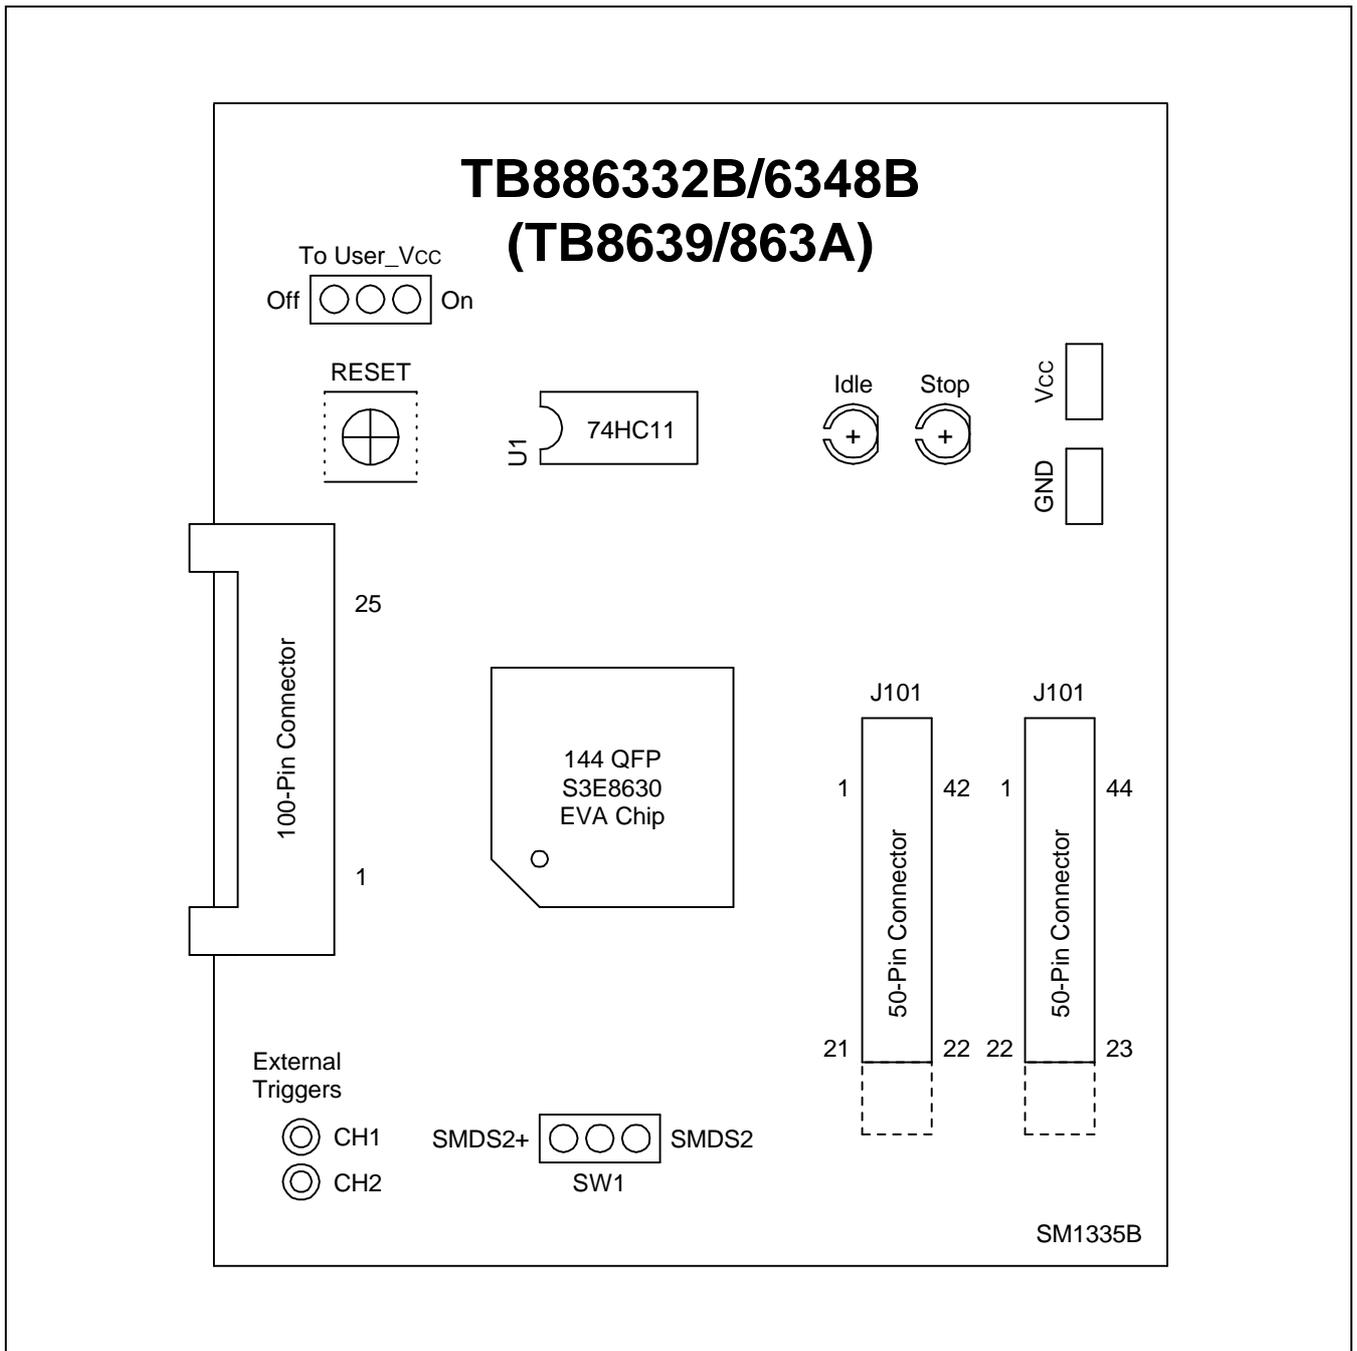

Figure 23-2. TB886332B/6348B (TB8639/863A) Target Board Configuration

TB886424A (TB8647) TARGET BOARD

The TB886424A (TB8647) target board is used for the S3C8647 microcontroller. It is supported by the SMDS2+ development system.
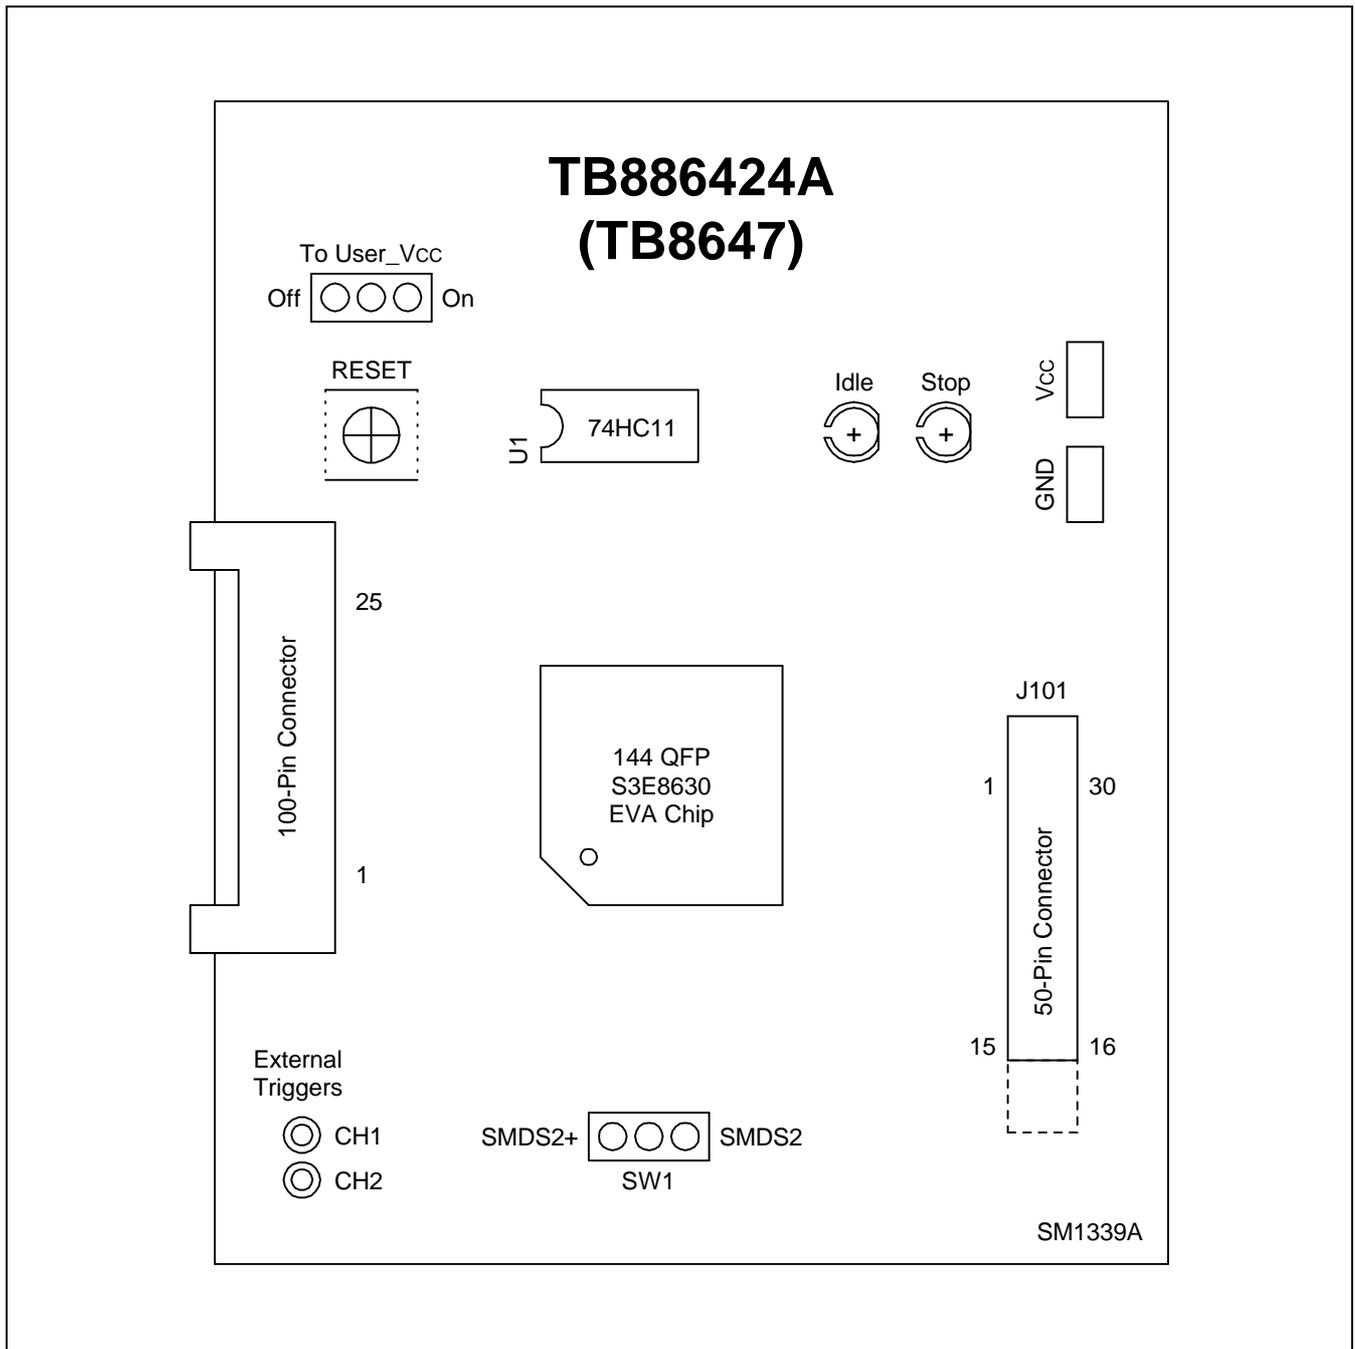

Figure 23-3. TB886424A (TB8647) Target Board Configuration

**Table 23-1. Power Selection Settings for TB886332B/TB886348B (TB8639/863A)**

| "To User_Vcc" Settings	Operating Mode	Comments
To User_Vcc OFF ⭕●● ON	TB886332B TB886348B (TB8639/863A) — V_{CC} → Target System ← V_{SS} V_{CC} | SMDS2/SMDS2+	The SMDS2/SMDS2+ supplies V_{CC} to the target board (evaluation chip) and the target system.
To User_Vcc OFF ●●⭕ ON	TB886332B TB886348B (TB8639/863A) — External V_{CC} → Target System ← V_{SS} V_{CC} | SMDS2/SMDS2+	The SMDS2/SMDS2+ supplies V_{CC} only to the target board (evaluation chip). The target system must have its own power supply.

SMDS2+ SELECTION (SAM8)

In order to write data into program memory that is available in SMDS2+, the target board should be selected to be for SMDS2+ through a switch as follows. Otherwise, the program memory writing function is not available.

**Table 23-3. The SMDS2+ Tool Selection Setting**

"SW1" Setting	Operating Mode
SMDS2 ⬤⬤ SMDS2+	

Table 23-4. Using Single Header Pins as the Input Path for External Trigger Sources

Target Board Part	Comments
EXTERNAL TRIGGERS ◎ CH1 ◎ CH2	 Connector from external trigger sources of the application system You can connect an external trigger source to one of the two external trigger channels (CH1 or CH2) for the SMDS2+ breakpoint and trace functions.
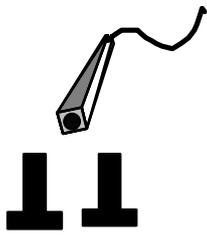

IDLE LED

This LED is ON when the evaluation chip (S3E8630) is in idle mode.

STOP LED

This LED is ON when the evaluation chip (S3E8630) is in stop mode.
