## Low Voltage Electroluminescent Lamp Driver

- +2.2V to +4.5V Battery Operation
- DC-to-AC Converter Produces Up To 220V<sub>PP</sub> for EL Display Panels
- Single Resistor Controlled Internal Oscillator
- Low Current Standby Mode
- Features
  - High Efficiency Super Driver Architecture
  - Uses Small 470μH Coil

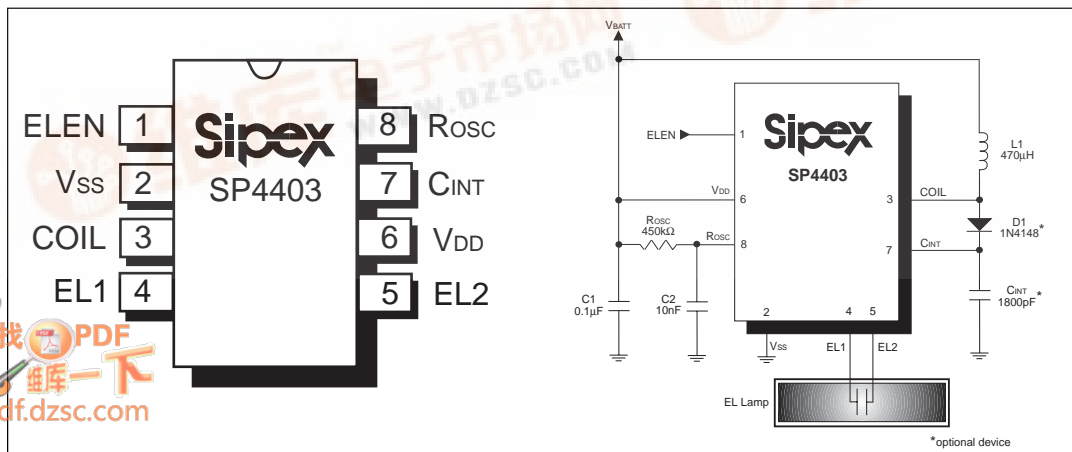

### APPLICATIONS

- Pagers
- Cellular Phones
- PDAs

### DESCRIPTION

The **SP4403** is a high voltage output DC-AC inverter specifically designed to drive electroluminescent lamps to backlight liquid crystal displays, keypads, and backlit readouts used in battery operated portable equipment. The **SP4403** will operate from a +2.2V to +4.5V battery source. The device features a low power shutdown mode which draws less than 100nA (typical), ideal for low power portable products. One external inductor is required to generate the high voltage AC output. One external resistor is used to select the internal oscillator frequency. The **SP4403** is ideal for portable applications such as cellular phones, PDAs, and other portable applications using LCDs in dim or low light environments. The **SP4403** is offered in 8 pin μSOIC packages.

\*optional device

## ABSOLUTE MAXIMUM RATINGS

These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

Power Supply,  $V_{BATT}$ .....7.0V  
 Input Voltages, ELEN (pin 1).....-0.5V to ( $V_{DD}+0.5V$ )  
 Lamp Outputs.....250V<sub>PP</sub>  
 Operating Temperature.....-40°C to +85°C  
 Storage Temperature.....-65°C to +150°C

### Power Dissipation Per Package

8-pin NSOIC (derate 6.51mW/°C above +70°C).....550mW  
 8-pin  $\mu$ SOIC (derate 4.85mW/°C above +70°C).....400mW

Peak to Peak Output Voltage, $V_{PP}$	150 180	190 210		$V_{PP}$	$V_{DD} = V_{COIL} = +3.0V$ $V_{DD} = V_{COIL} = +4.5V$

## PINOUT

## PIN ASSIGNMENTS

Pin 1 — ELEN — Electroluminescent Lamp Enable. When driven HIGH, this input pin enables the EL driver output EL1 and EL2 (pins 4 and 5, respectively) to the EL lamp.

Pin 2 — V<sub>SS</sub> — Power Supply Common. Connect to the lowest circuit potential, typically ground.

Pin 3 — COIL — Coil. The inductor for the EL lamp is connected from V<sub>BATT</sub> to this input pin.

Pin 4 — EL1 — Electroluminescent Lamp. This is a lamp driver output pin to connect to the EL lamp.

Pin 5 — EL2 — Electroluminescent Lamp. This is a lamp driver output pin to connect to the EL lamp.

Pin 6 — V<sub>DD</sub> — Positive Battery Power Supply. Connect such that  $+2.2V < V_{DD} < +4.5V$ .

Pin 7 — C<sub>INT</sub> — Integrator Capacitor. An Integrator Capacitor (470pF typical) connected from this pin to ground filters out any coil switching spikes or ripple present in the outer waveform to the EL lamp. Connecting a fast recovery diode from COIL (pin 3) to this input pin increases the light output of the EL lamp.

Pin 8 — R<sub>OSC</sub> — Oscillator Resistor. Connecting a 450k $\Omega$  resistor to this input pin sets the frequency of the internal clock.

## DESCRIPTION

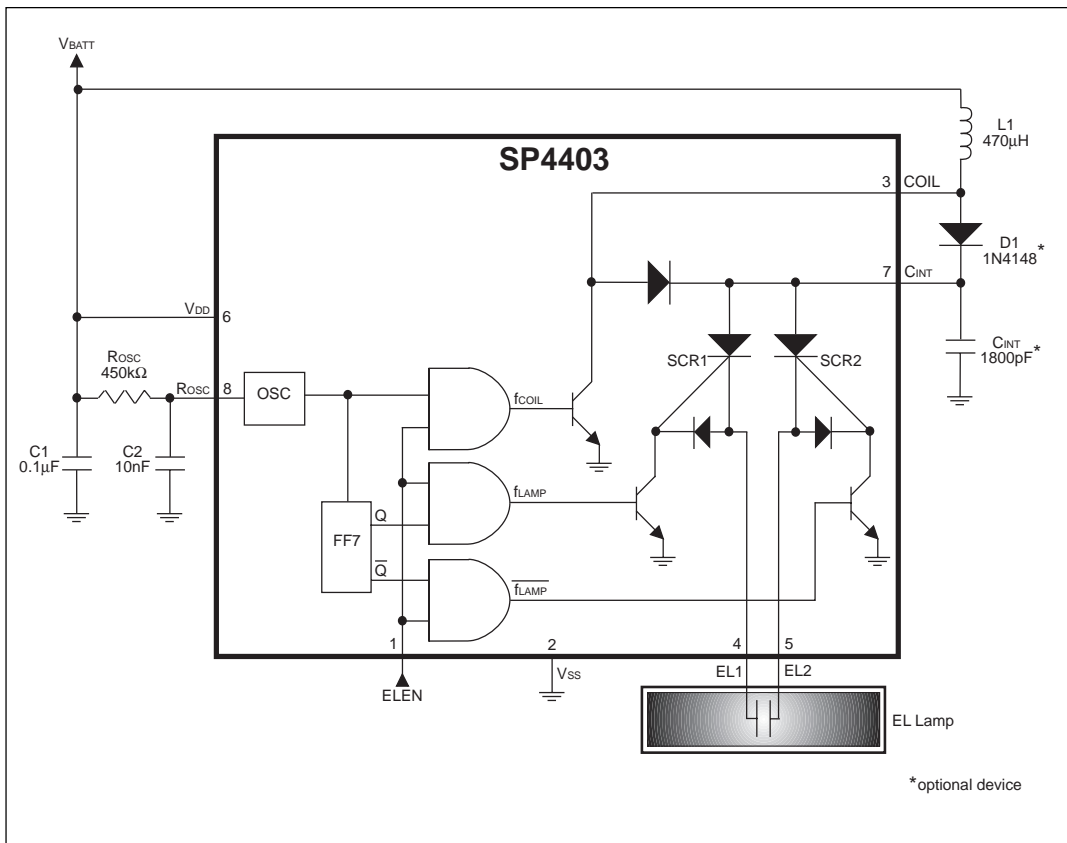

The **SP4403** contains a DC-AC inverter that can produce an AC output of  $180V_{pp}$  from a  $+2.2V$  to  $+4.5V$  input voltage. An internal block diagram of the **SP4403** can be found in *Figure 1*.

The **SP4403** is built on **Sipex's** dielectrically isolated BiCMOS process that provides the isolation required to separate the high voltage AC signal used to drive the EL lamp from the low voltage logic and signal processing circuitry. This ensures latch-up free operation in the interface between the low voltage CMOS circuitry and the high voltage bipolar circuitry. The **SP4403** is ideal for applications driving EL lamps to backlight LCD displays, key panels, and other backlit readouts used in battery operated portable equipment.

A total of only six external components are required for the standard operation of the **SP4403**: an inductor, a fast recovery diode, three capacitors and a resistor. A diagram of the **SP4403** in a typical application can be found in *Figure 2*.

## Electroluminescent Technology

An EL lamp is basically a strip of plastic that is coated with a phosphorous material which emits light (fluoresces) when a high voltage ( $>40V$ ) which was first applied across it, is removed or reversed. Long periods of DC voltages applied to the material tend to breakdown the material and reduce its lifetime. With these considerations in mind, the ideal signal to drive an EL lamp is a high voltage sine wave. Traditional approaches to achieving this type of waveform included discrete circuits incorporating a transformer, transistors, and several resistors and capacitors.

*Figure 1. Internal Diagram of the SP4403*

This approach is large and bulky, and cannot be implemented in most hand held equipment. Sipex now offers low power single chip driver circuits specifically designed to drive small to medium sized electroluminescent panels. All that is required for the EL driver circuitry is an external inductor and an external capacitor.

## Market Applications

Electroluminescent backlighting is ideal when used with LCD displays, keypads, or other backlit readouts. Its main use is to illuminate displays in dim to dark conditions for momentary periods of time. EL lamps typically consume less power than LEDs or incandescent bulbs making them ideal for battery powered products. Also, EL lamps are able to evenly light an area without creating any undesirable "hot spots" in the display.

## THEORY OF OPERATION

The **SP4403** is a DC-AC inverter made up of: 1. The Oscillator/Frequency Divider, 2. The Coil, and 3. The Switched H-bridge Network. Further details of each element follow.

### The Oscillator/Frequency Divider

The oscillator provides the **SP4403** with an on-chip clock used to control the coil switch ( $f_{COIL}$ ) and the H-bridge network ( $f_{LAMP}$  and  $f_{LAMP}$ ). Although the oscillator frequency can be varied to optimize the lamp output, the ratio of  $f_{COIL}/f_{LAMP}$  will always equal 128.

*Figure 1* shows the oscillator output driving the coil and the output of the oscillator with 7 flip flops driving the lamp. The suggested oscillator frequency is 50kHz ( $R_{OSC} = 450k\Omega$ ) for  $f_{COIL}$ . The oscillator output is internally divided down by 7 flip flops to create a second internal control signal at 390Hz for  $f_{LAMP}$ .

### The Coil

The supply  $V_{BATT}$  can range from +2.2V to +4.5V.  $V_{BATT}$  should not exceed the maximum coil current specification. The majority of the current goes through the coil and is typically much greater than  $I_{DD}$ .

The coil is an external component connected from  $V_{BATT}$  to pin 3 of the **SP4403**. Energy is stored in the coil according to the equation

*Figure 2. Typical Application Circuit for the SP4403, Set for a Square Wave Output with  $C_{INT} = 0.1\mu F$*

$E_L = 1/2LI_p^2$  where  $I_p$ , to the first approximation, is the product  $I_p = (t_{ON})(V_{BATT} - V_{CE})/L$ , where  $t_{ON}$  is the time it takes for the coil to reach its peak current,  $V_{CE}$  is the voltage drop across the internal NPN switch transistor, and  $L$  is the inductance of the coil. When the NPN transistor switch is off, the energy is forced through an internal diode which drives the switched H-bridge network. This energy recovery is directly related to the brightness of the EL lamp output. There are many variations among coils; magnetic material differences, winding differences and parasitic capacitances. For suggested coil suppliers, refer to *Page 7*.

The  $f_{COIL}$  signal controls a switch that connects the end of the coil at pin 3 to ground or to open circuit. The  $f_{COIL}$  signal is a 90% duty cycle signal switching at the oscillator frequency, 50kHz. During the time when the  $f_{COIL}$  signal is HIGH, the coil is connected from  $V_{BATT}$  to ground and a charged magnetic field is created in the coil. When the  $f_{COIL}$  signal is LOW, the ground connection is switched open, the field collapses, and the energy in the inductor is forced to flow toward the high voltage H-bridge switches.  $f_{COIL}$  will send an array of charge pulses (see *Figure 4*) to the lamp. Each pulse increases the voltage drop across the lamp in discrete steps. As the voltage potential approaches its maximum, the steps become smaller (see *Figure 3*).

## The Switched H-Bridge Network

The H-bridge consists of two SCR structures that act as high voltage switches. These two switches control the polarity of how the lamp is charged. The SCR switches are controlled by the  $f_{LAMP}$  signal which is the oscillator frequency divided by 128. For a 50kHz oscillator, the 7 flip flops will drive  $f_{LAMP} = 390\text{Hz}$ .

When the energy from the coil is released, a high voltage spike is created triggering the SCR switches. The direction of current flow is determined by which SCR is enabled. One full cycle of the H-bridge will create 128 voltage steps from ground to 80V (typical) on EL1 and EL2 (pins 4 and 5, respectively) which are 180 degrees out of phase from each other (see *Figure 5*). A differential representation of the output is shown in *Figure 6*.

## Fine Tuning Performance

Circuit performance of the **SP4403** can be improved with some of the following suggestions:

**Increase EL Lamp Light Output:** By connecting a fast recovery diode from COIL (pin 3) to  $C_{INT}$  (pin 7), the internal diode of the switched H-bridge network is bypassed resulting in an increase in light output at the EL lamp. We suggest a fast recovery diode, such as the industry standard 1N4148, be used for D1. This circuit connection can be found in *Figure 2*.

**Square Wave Output Waveform to the EL Lamp:** A 470pF capacitor at  $C_{INT}$  (pin 13) will act as an integrating capacitor, filtering out any coil switching spikes or ripple in the output waveform to the EL lamp (shown in *Figure 1*).

A designer may change the output waveform to a square wave by using a 0.1 $\mu\text{F}$  capacitor (shown in *Figure 2*) at  $C_{INT}$  (pin 13).

## Printed Circuit Board Layout Suggestions:

The **SP4403**'s high-frequency operation makes PCB layout important for minimizing ground bounce and noise. Keep the IC's GND pin and the ground leads of C1 and  $C_{INT}$  in *Figure 2* less than 0.2in (5mm) apart. Also keep the connections to L1 (pin 3) as short as possible. To maximize output power and efficiency and minimize output ripple voltage, use a ground plane and solder the IC's  $V_{SS}$  (pin 2) directly to the ground plane.

## EL Lamp Driver Design Challenges

There are many variables which can be optimized for specific applications. The amount of light emitted is a function of the voltage applied to the lamp, the frequency at which it is applied, the lamp material, the lamp size, and the inductor used. **Sipex** supplies characterization charts to aid the designer in selecting the optimum circuit configuration (see *Figures 7 to 14*).

**Sipex** will perform customer application evaluations, using the customer's actual EL lamp to determine the optimum operating conditions for specific applications. For customers considering an EL backlighting solution for the first time, **Sipex** is able to offer retrofitted solutions to the customer's existing LED or non-backlit product for a thorough electrical and cosmetic evaluation. Please contact your local Sales Representative for **Sipex** or the **Sipex** factory directly to initiate this valued service.
