Electroluminescent Lamp Driver
# Low Voltage Applications

- Low Voltage, Single Battery Operation ($V_{BATTERY} \geq 1.1$ VDC)
- DC to AC Inverter for EL Backlit Display Panels
- Externally Adjustable Internal Oscillator
- Low Current Standby Mode

APPLICATIONS
- Pagers
- Digital Watches
- Backlit LCD Displays

DESCRIPTION

The **SP4425** is a high voltage output DC-AC converter that can operate from a single 1.5 VDC power supply. The **SP4425** is capable of supplying up to 220 V_{PP} signals, making it ideal for driving electroluminescent lamps. The device features 1 µA (typical) standby current for use in low power portable products. One external inductor is required to generate the high voltage charge and one external capacitor is used to select the oscillator and lamp frequencies. The **SP4425** is offered in both an 8-pin narrow SOIC and 8-pin micro SOIC package. For delivery in die form, please consult the factory.

V_{SS}	143.5	-412.0
C_{OSC}	-790.0	-157.5
HON	-785.5	402.0

NOTES:
1. Dimensions are in Microns unless otherwise noted.
2. Bonding pads are 125x125 typical.
3. Outside dimensions are maximum, including scribe area.
4. Die thickness is 10 mils +/- 1.
5. Pad center coordinates are relative to die center.
6. Die size 74 x 44 mils.

PIN DESCRIPTION
Pin 1 – C_{OSC}- Capacitor input 1, connect Capacitor from V_{SS} to Pin 1 to set C_{OSC} frequency.

Pin 2 – V_{SS}- Power supply common, connect to ground.

Pin 3 – Coil- Coil input, connect coil from V_{DD} to pin 3.

Pin 4 – D1- Diode Cathode connection.
　　　– C_{INT}- Integrator capacitor, connect capacitor from pin 4 to ground to minimize coil glitch energy.

Pin 5 – Lamp- Lamp driver output2, connect to EL lamp.

Pin 6 – Lamp- Lamp driver output1, connect to EL lamp.

Pin 7 – V_{DD}- Power supply for driver, connect to system V_{DD}.

Pin 8 – HON- Enable for driver operation, high = active; low = inactive.

THEORY OF OPERATION

The **SP4425** is made up of three basic circuit elements, an oscillator, coil, and switched H-bridge network. The oscillator provides the device with an on-chip clock source used to control the charge and discharge phases for the coil and lamp. An external capacitor connected between pins 1 and V_{SS} allows the user to vary the oscillator frequency. For a given choice of coil inductance there will be an optimum C_{OSC} Capacitor value that gives the maximum light output.

The suggested oscillator frequency is 25.6kHz (C_{OSC}=180pF). The oscillator output is internally divided to create the control signal for f_{LAMP}. The oscillator output is internally divided down by 6 flip flops, a 25.6kHz signal will be divided into 6 frequency levels: 12.8kHz, 6.4kHz, 3.2kHz, 1.6kHz, 800Hz, and 400Hz. The oscillator output (25.6kHz) is used to drive the coil (see *figure 2* on *page 11*) and the sixth flip flop output (300Hz) is used to drive the lamp. Although the oscillator frequency can be varied to optimize the lamp output, the ratio of f_{COIL}/f_{LAMP} will always equal 64.

The coil is an external component connected from $V_{BATTERY}$ to pin 3 of the **SP4425**. $V_{BATTERY}$= 1.5 VDC with a 470µH/4Ω coil are typical conditions. Energy is stored in the coil according to the equation E_L=1/2LI², where I is the peak current flowing in
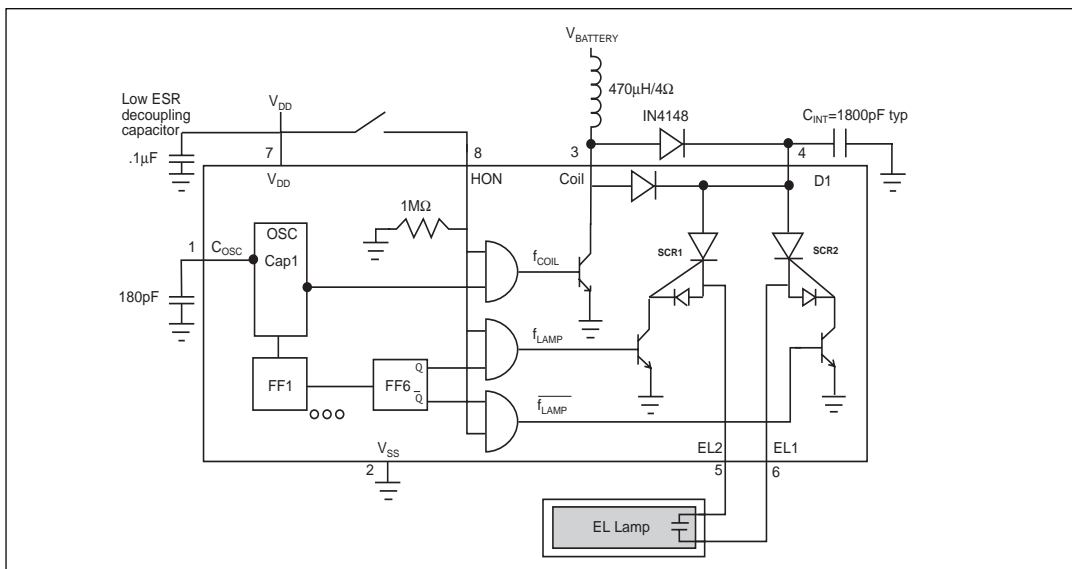

SP4425 Schematic

the inductor. The current in the inductor is time dependent and is set by the "ON" time of the coil switch: $I=(V_L/L)t_{ON}$, where V_L is the voltage across the inductor. At the moment the switch closes, the current in the inductor is zero and the entire supply voltage (minus the V_{SAT} of the switch) is across the inductor. The current in the inductor will then ramp up at a linear rate. As the current in the inductor builds up, the voltage across the inductor will decrease due to the resistance of the coil and the "ON" resistance of the switch: $V_L=V_{BATTERY}-IR_L-V_{SAT}$. Since the voltage across the inductor is decreasing, the current ramp-rate also decreases which reduces the current in the coil at the end of t_{ON} the energy stored in the inductor per coil cycle and therefore the light output. The other important issue is that maximum current (saturation current) in the coil is set by the design and manufacturer of the coil. If the parameters of the application such as $V_{BATTERY}$, L, R_L or t_{ON} cause the current in the coil to increase beyond its rated I_{SAT}, excessive heat will be generated and the power efficiency will decrease with no additional light output.

The majority of the current goes through the coil and typically less than 2mA is required for V_{DD} of the **SP4425**. V_{DD} can range from 1.5V to 3.0V; it is not necessary that $V_{DD}=V_{BATTERY}$. Coils are also a function of the core material and winding used -- performance variances may be noticeable from different coil suppliers. The Sipex **SP4425** is final tested at 1.5V using a 470µH/4Ω coil from Toko, and a 2mH/44Ω coil from Matsushita at 3V. For suggested coil sources see *page 12*.

The f_{COIL} signal controls a switch that connects the end of the coil at pin 3 to ground or to open circuit. The f_{COIL} signal is a 90% duty cycle signal switching at the oscillator frequency. During the time when the f_{COIL} signal is high, the coil is connected from $V_{BATTERY}$ to ground and a charged magnetic field is created in the coil. During the low part of f_{COIL}, the ground connection is switched open, the field collapses and the energy in the inductor is forced to flow toward the lamp. f_{COIL} will send 32 of these charge pulses (see *figure 2* on *page 11*) lamp, each pulse increases the voltage drop across the lamp in discrete steps. As the voltage potential approaches its maximum, the steps become smaller (see *figure 1* on *page 11*).

The H-bridge consists of two SCR structures that act as high voltage switches. These two switches control the polarity of how the lamp is charged. The SCR switches are controlled by the f_{LAMP} signal which is the oscillator frequency divided by 64. For a 25.6kHz oscillator, f_{LAMP}=400Hz.

When the energy from the coil is released, a high voltage spike is created triggering the SCR switches. The direction of current flow is determined by which SCR is enabled. One full cycle of the H-bridge will create a voltage step from ground to 80V (typical) on pins 5 and 6 which are 180 degrees out of phase with each other (see *figure 3* on *page 11*). A differential view of the outputs is shown in *figure 4* on *page 11*.

Layout Considerations

The **SP4425** circuit board layout must observe careful analog precautions. For applications with noisy power supply voltages, a 0.1µF low ESR decoupling capacitor must be connected from Vdd to ground. Any high voltage traces should be isolated from any digital clock traces or enable lines. A solid ground plane connection is strongly recommended. All traces to the coil or to the high voltage outputs should be kept as short as possible to minimize capacitive coupling to digital clock lines and to reduce EMI emissions.

Integrator Capacitor

An integrating capacitor must be placed from pin 4 (D1) to ground in order to minimize glitches associated with switching the coil. A capacitor at this point will collect the high voltage spikes and will maximize the peak to peak voltage output. High resistance EL lamps will produce more pronounced spiking on the EL output waveform; adding the C_{INT} capacitor will minimize the peaking and increase the voltage output at each coil step. The value of the integrator capacitor is application specific typical values can range from 500pF to 0.1µF. No integrator capacitor or very small values (500pF) will have a minor effect on the output, whereas a 0.1µF capacitor will cause the output to charge and discharge rapidly creating a square wave output. For most applications an 1800pF integrator capacitor is suitable.

Electroluminescent Technology

What is electroluminescence?
An EL lamp is basically a strip of plastic that is coated with a phosphorous material which emits light (fluoresces) when a high voltage (>40V) which was first applied across it, is removed or reversed. Long periods of DC voltages applied to the material tend to breakdown the material and reduce its lifetime. With these considerations in mind, the ideal signal to drive an EL lamp is a high voltage sine wave. Traditional approaches to achieving this type of waveform included discrete circuits incorporating a transformer, transistors, and several resistors and capacitors. This approach is large and bulky, and cannot be implemented in most hand held equipment. **Sipex** now offers low power single chip driver circuits specifically designed to drive small to medium sized electroluminescent panels if all that is required is one external inductor fast recovery diode and two capacitors.

Electroluminescent backlighting is ideal when used with LCD displays, keypads, or other backlit readouts. Its main use is to illuminate displays in dim to dark conditions for momentary periods of time. EL lamps typically consume less than LEDs or bulbs making them ideal for battery powered products. Also, EL lamps are able to evenly light an area without creating "hot spots" in the display.

The amount of light emitted is a function of the voltage applied to the lamp, the frequency at which it is applied, the lamp material used and its size, and lastly, the inductor used. Both voltage and frequency are directly related to light output. In other words as the voltage or the frequency of the EL output is increased the light output will also increase. The voltage has a much larger impact on light output than the frequency does. For example, an output signal of $168V_{PP}$ with a frequency of 500Hz can yield $15Cd/m^2$, in the same application a different EL driver could produce $170V_{PP}$ with a frequency of 450Hz and can also yield $15Cd/m^2$. Variations in peak to peak voltage and variations in lamp frequency are to be expected, light output will also vary from device to device however typical light output variations are usually not visually noticeable.
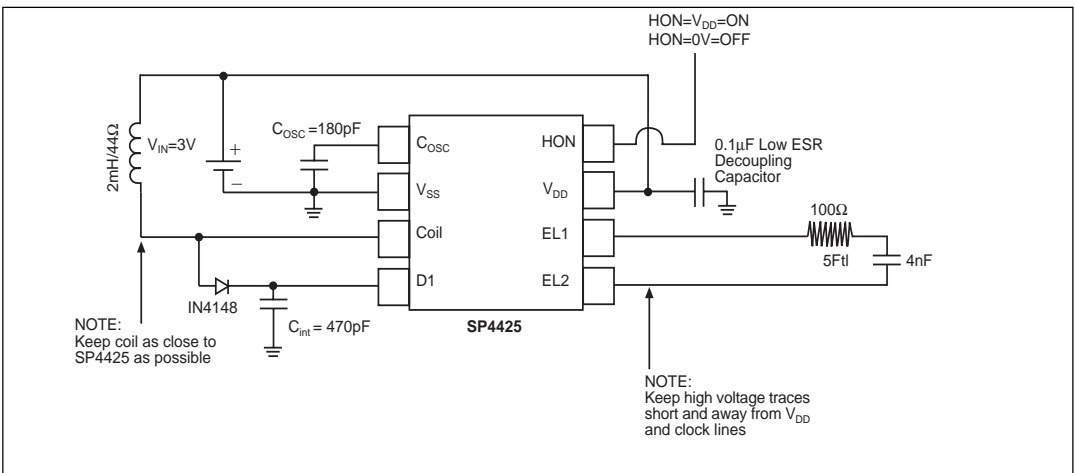

There are many variables which can be optimized for specific applications. **Sipex** supplies characterization charts to aid the designer in selecting the optimum circuit configuration (see *page 7* and *8*).
