FUNCTIONS**1. Switching power supply control circuit**

Incorporates a step-down switching power supply control function for the IGBT driver block power supply (V_p) or DC fan motor power supply.

When $DC_{out} = H$ ($VSENSE = H$) : Output driver = ON (switching power supply = OFF)

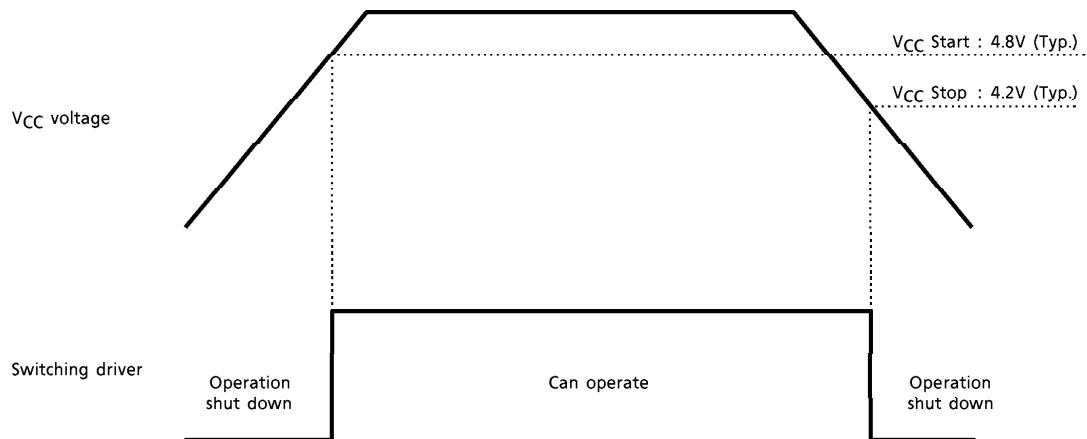

When $DC_{out} = L$ ($VSENSE = L$) : Output driver = OFF (switching power supply = ON)

2. UVLO (Under-Voltage Lock out) function

To prevent malfunction, a function is incorporated to shut down the switching power supply control block when the power supply voltage (V_{CC}) drops.

This function detects power supply voltage V_{CC} in the IC. If voltage is 4.8V or higher, the switching driver can operate. If voltage is 4.2V or lower, the switching driver is shut down.

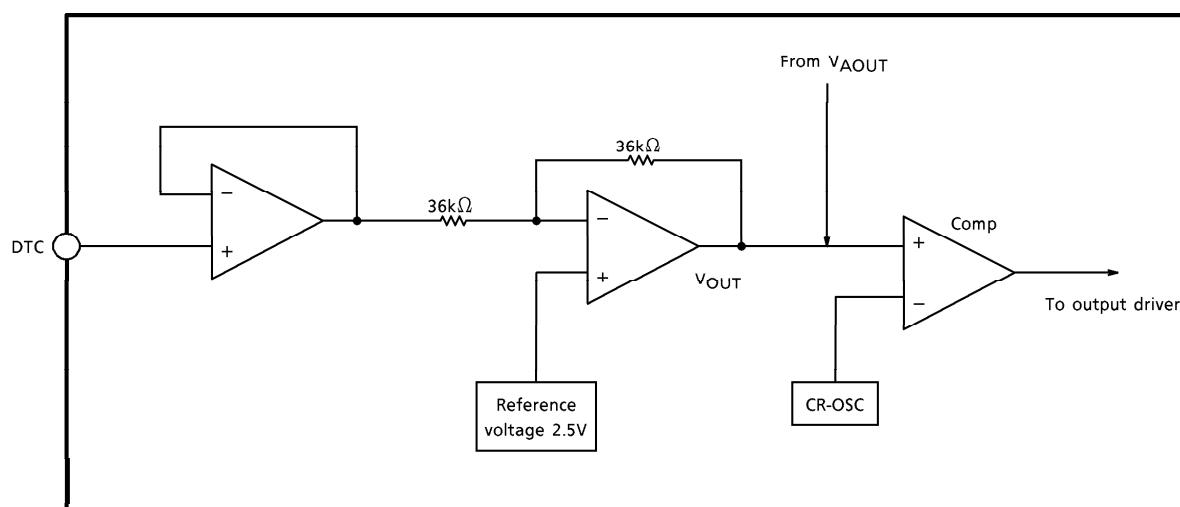

3. Dead time control function

Dead time control (DTC) is used to set the output pulse of the switching power supply control block to maximum duty.

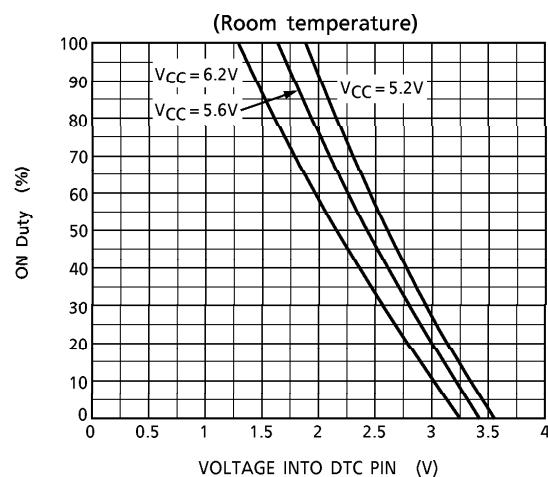

Depending on the DTC pin voltage, a maximum duty of up to 100% can be set.

DTC pin voltage low → V_{OUT} high → output driver duty large

DTC pin voltage high → V_{OUT} low → output driver duty small

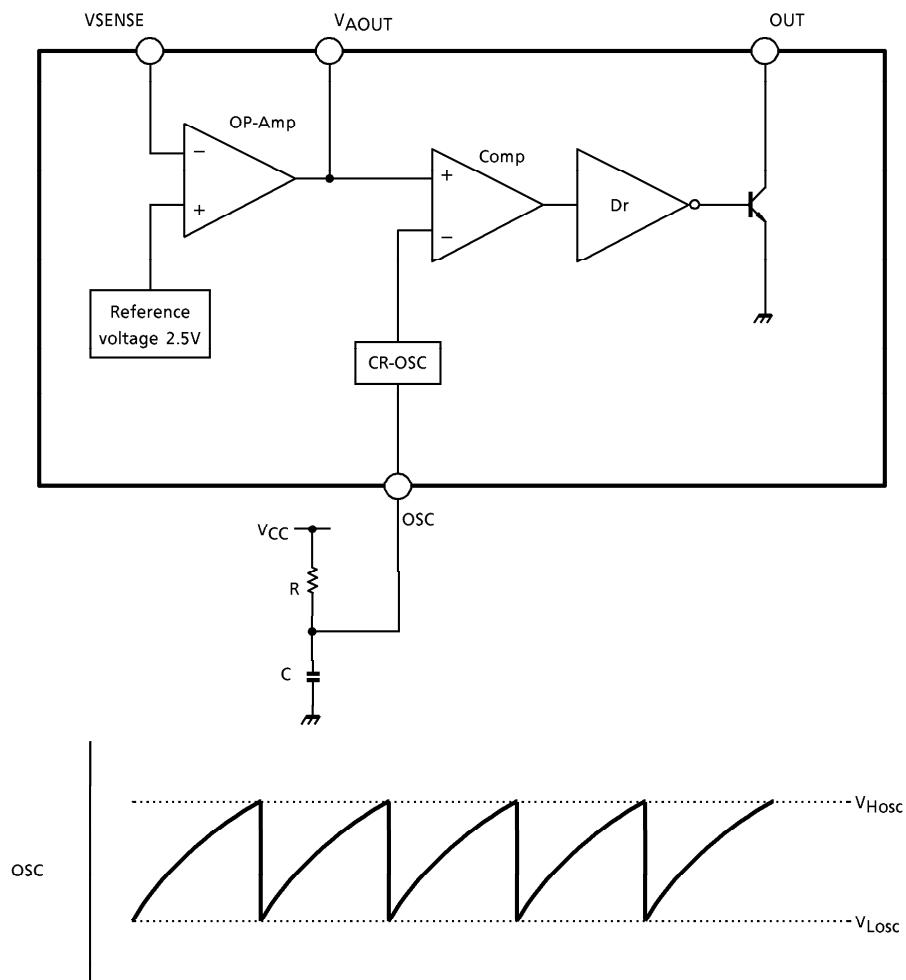

* Output on duty characteristics (reference)

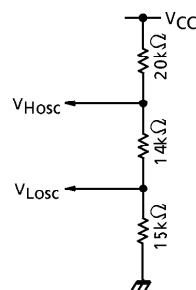

4. CR oscillator circuit

The oscillator for the switching power supply control is connected to an external capacitor and a resistor. This oscillator is used to set the switching frequency.

V_{Hosc} and V_{Losc} are obtained by dividing the V_{CC} using the resistance within the IC.

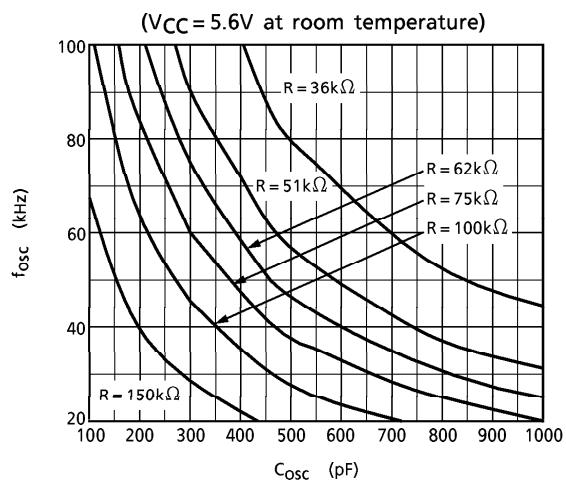

V_{Hosc} and V_{Losc} are set within the IC as shown in the diagram.

For the oscillation frequency setting, see the following graph.

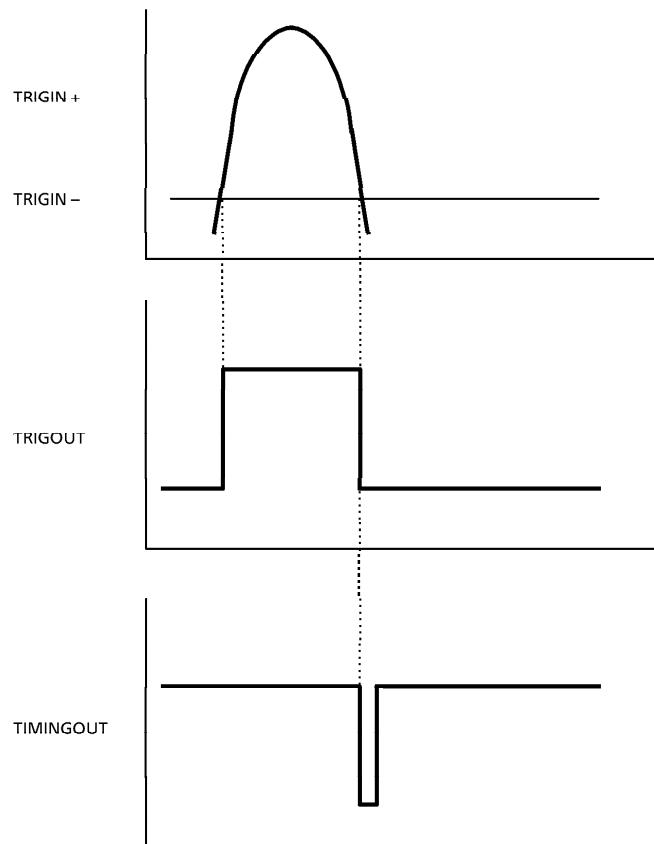

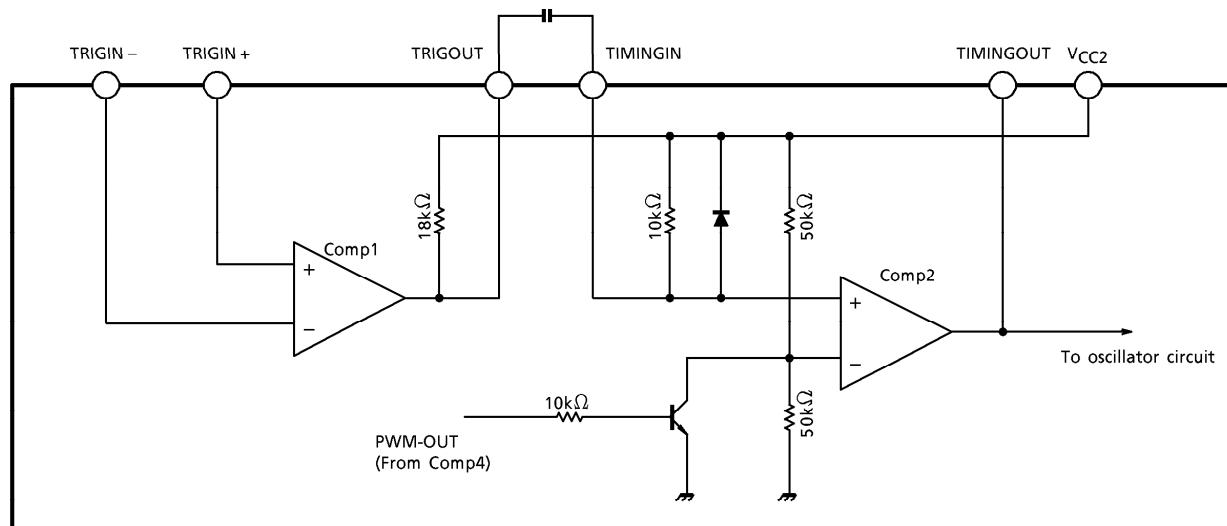

* Oscillation frequency characteristics of switching power supply block (reference)

5. Oscillation timing circuit (trigger comparator / timing comparator)

The trigger comparator detects the oscillation timing ; the timing comparator generates the timing signal.

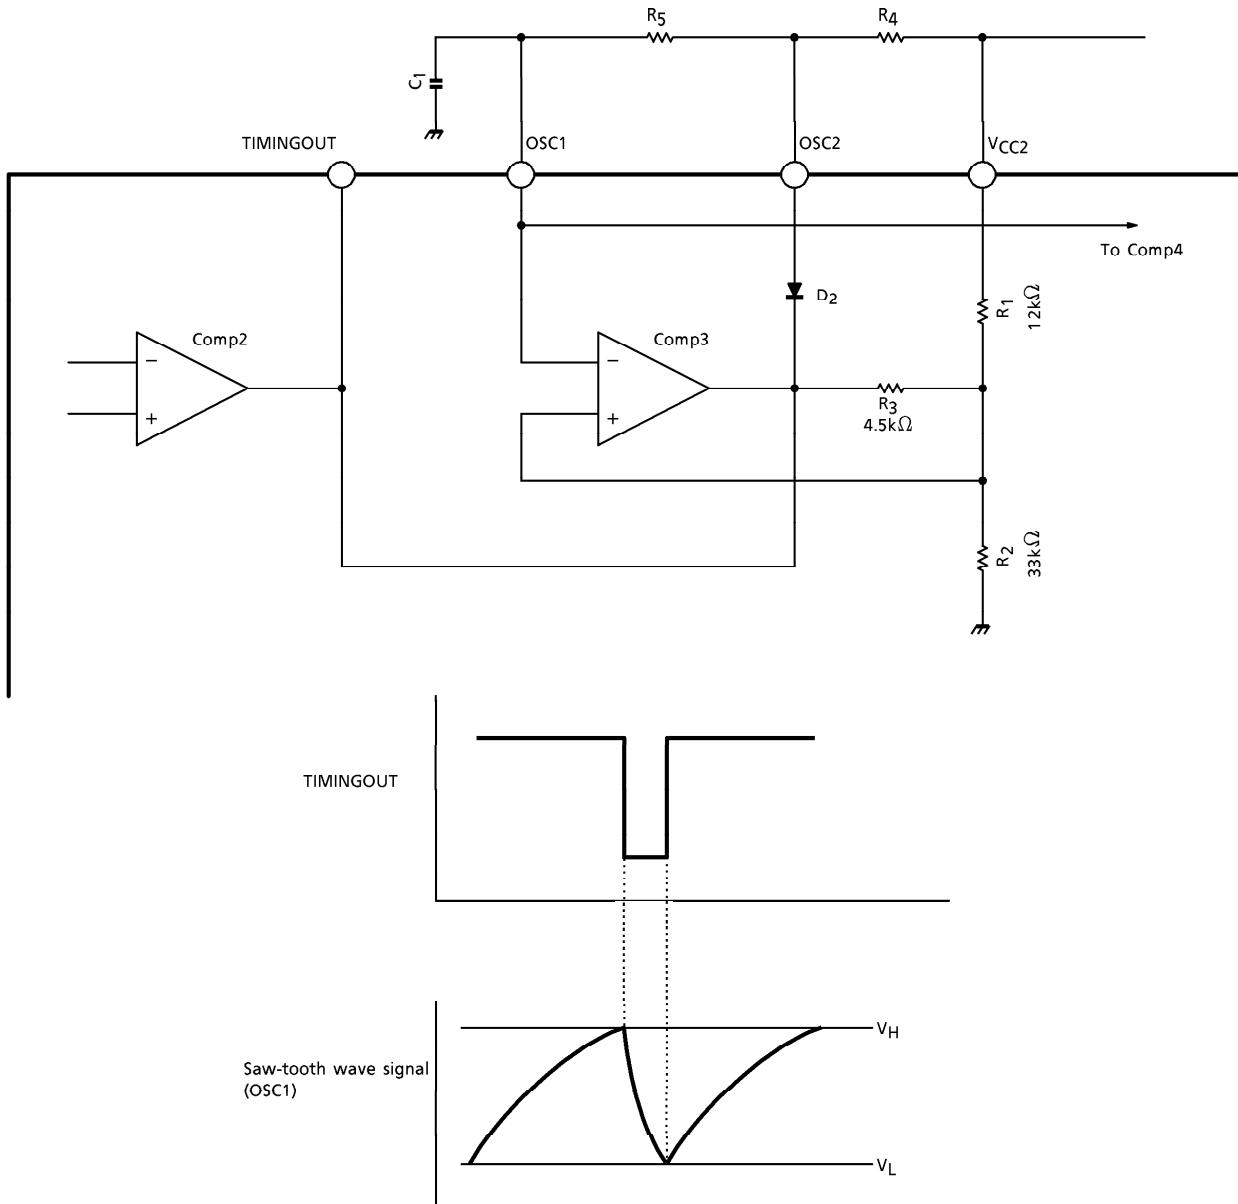

This timing signal is passed on to the next stage oscillator circuit.

6. Oscillator circuit 1 (Oscillation comparator)

This circuit generates a saw-tooth wave signal for the IGBT driver that starts on a timing signal from the oscillation timing circuit.

R_1 , R_2 and R_3 in the IC are used to set the oscillation amplitude of this saw-tooth wave signal.

Here, V_H and V_L are as follows :

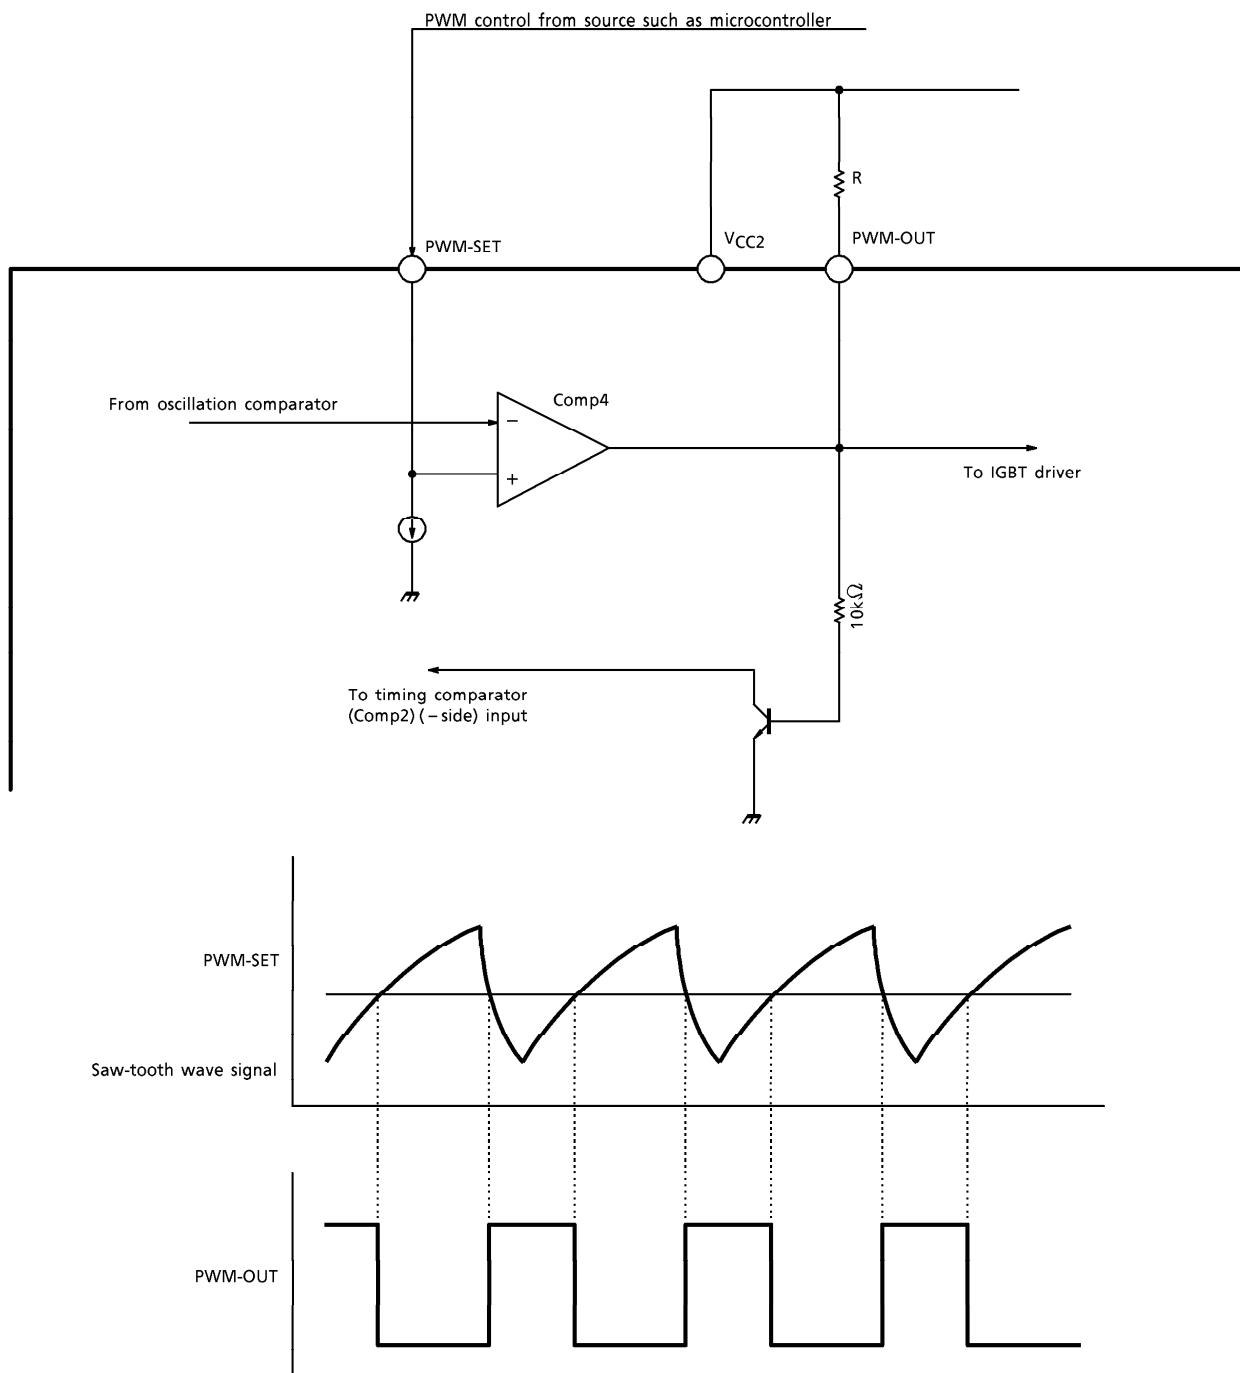

$$V_H = \frac{R_1}{R_1 + R_2} \times V_{CC2} (V)$$

$$V_L = \frac{R_3}{R_1 + R_3} \times (V_{CC2} - V_{OL}) + V_{OL} (V)$$

7. Oscillator circuit 2 (PWM comparator)

The width of the pulse for the IGBT driver is set by the saw-tooth wave signal from the oscillation comparator and the external output adjustment level.

Input to the PWM-SET pin the PWM output adjustment level from a source such as the microcontroller.

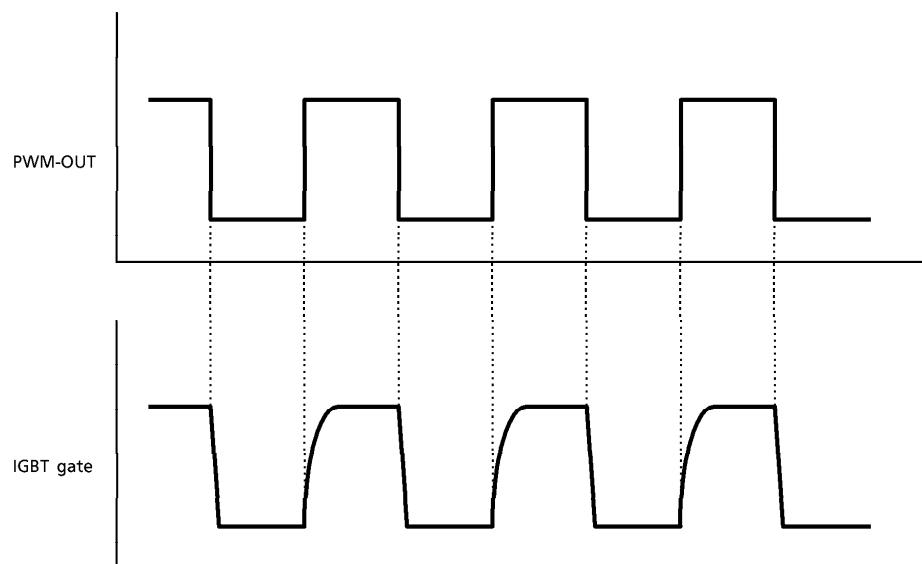

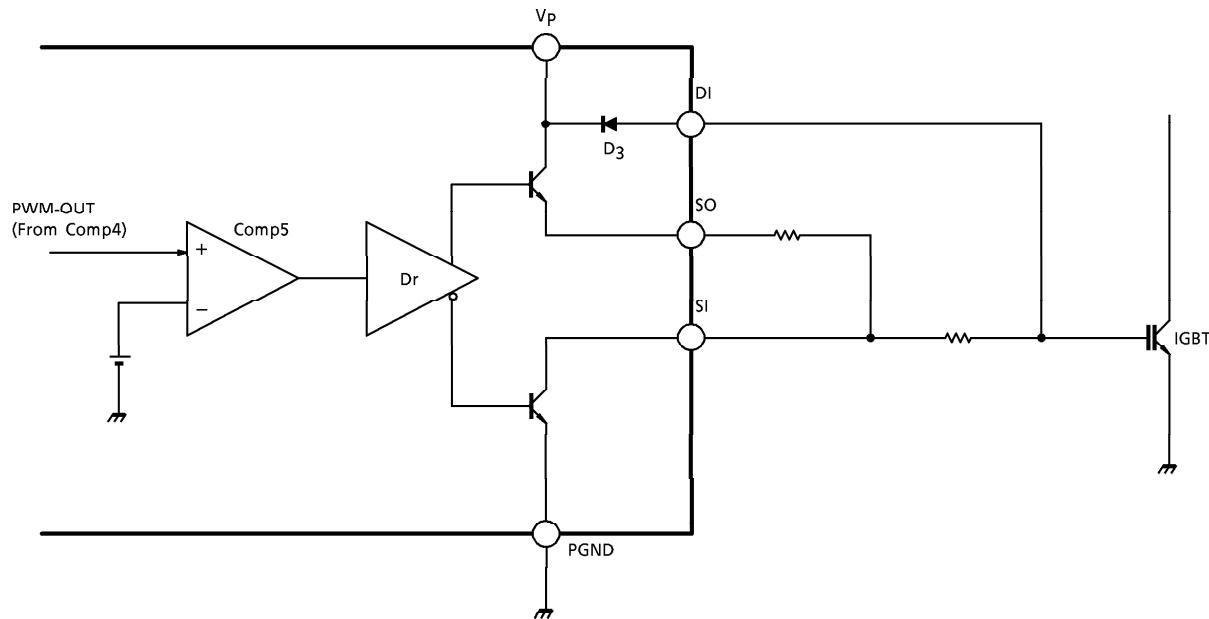

8. IGBT driver

The IGBT driver can be directly driven by a PWM signal from the PWM control block.

Source current : -200mA (max)

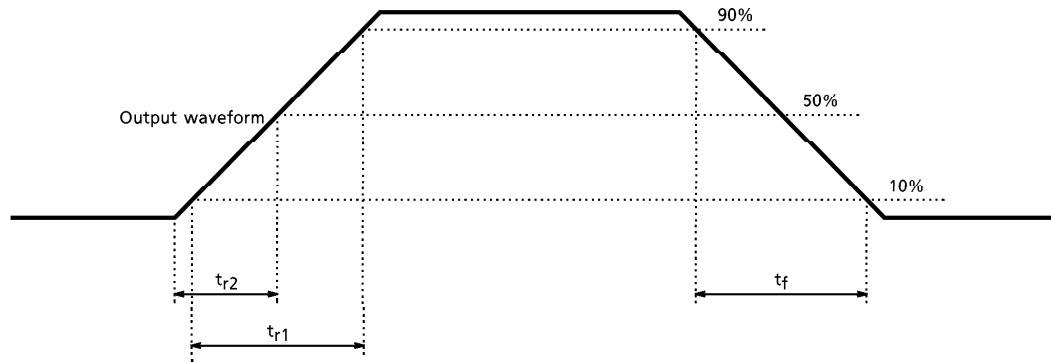

Sink current : 1A (max)

In addition, the device incorporates an IGBT gate protector diode to prevent malfunction at power on.

9. Low voltage detection function

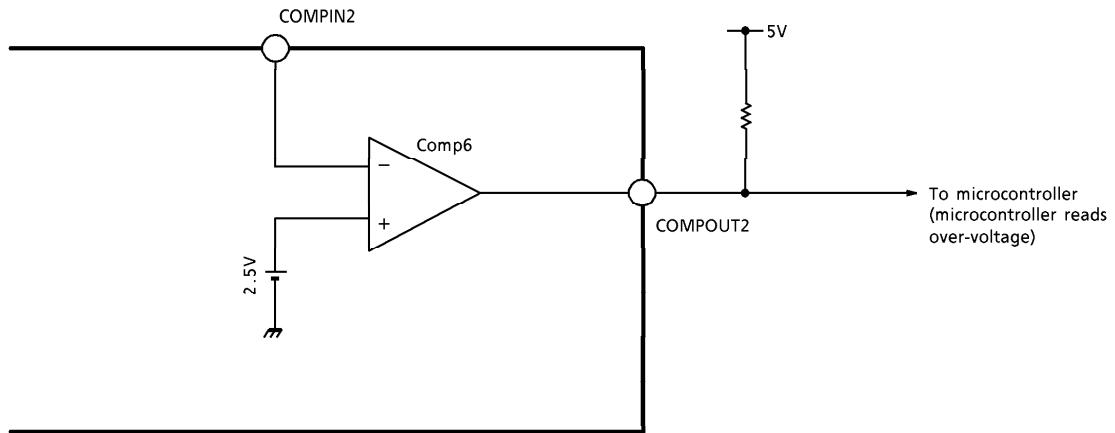

The device incorporates a comparator to detect a fall in voltage, for example at an outage, and output a detection signal to an external device such as a microcontroller.

10. Over-voltage detection function 1

The device incorporates a comparator to detect over-voltage and output a detection signal to an external device such as a microcontroller.

11. Over-voltage detection function 2

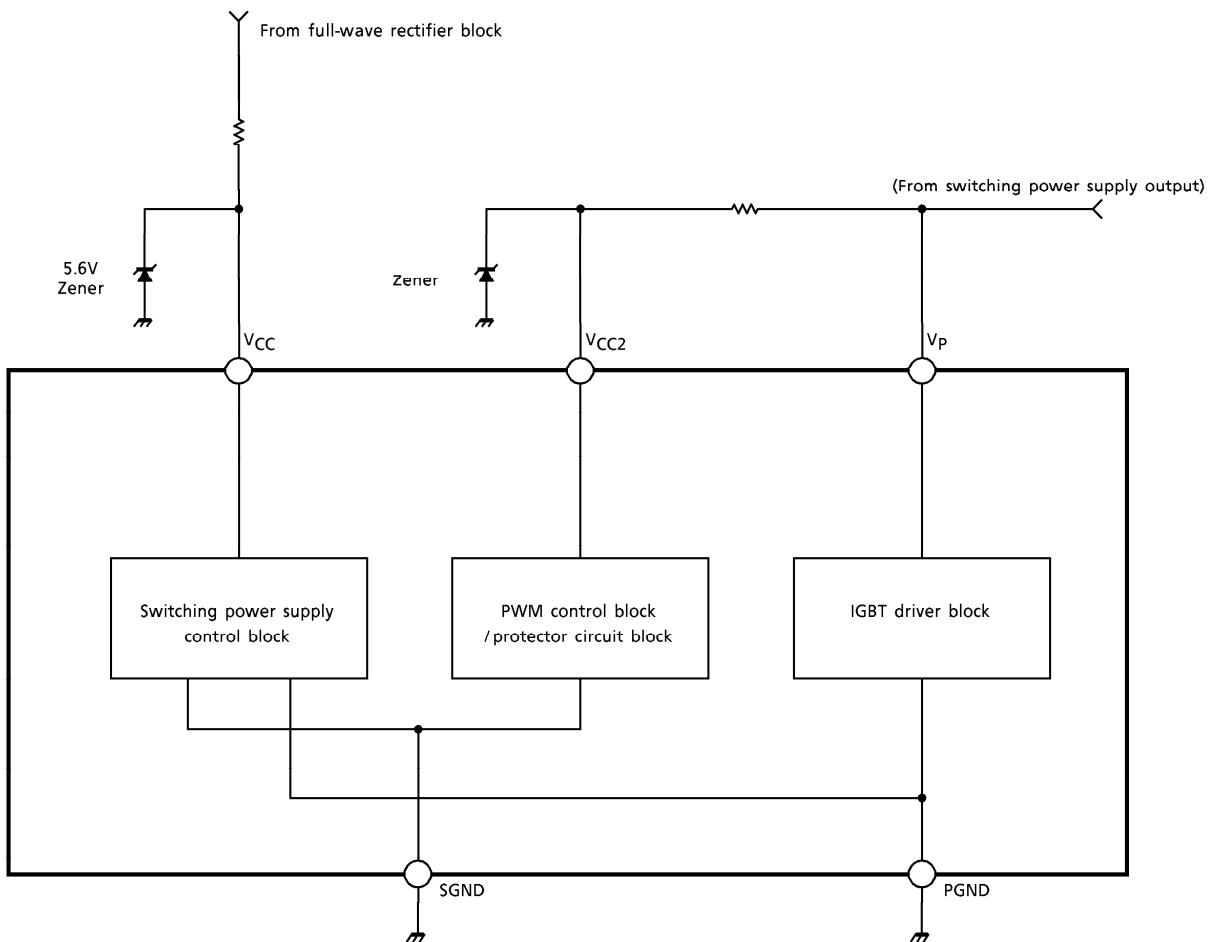

The device incorporates a function to detect over-voltages such as surges and to stop the PWM signal that drives the IGBT.

12. Power supply / GND

The device's power supply and GND are as follows. (See block diagram.)

- (1) Switching power supply control block V_{CC} / SGND / PGND (switching driver only)
- (2) PWM control block / protector circuit block V_{CC2} / SGND
- (3) IGBT driver block V_P / PGND
