

QUAD DIFFERENTIAL PECL DRIVERS

FEATURES

- Functional Replacements for the Agere BDG1A, BPNGA and BDGLA
- Pin-Equivalent to the General-Trade 26LS31 Device
- 2.0 ns Maximum Propagation Delays
- 0.15 ns Output Skew Typical Between \pm Pairs
- Capable of Driving 50- Ω Loads
- 5.0-V or 3.3-V Supply Operation
- TB5D1M Includes Surge Protection on Differential Outputs
- TB5D2H No Line Loading When $V_{CC} = 0$
- Third State Output Capability
- -40°C to 85°C Operating Temp Range
- ESD Protection HBM > 3 kV and CDM > 2 kV
- Available in Gull-Wing SOIC (JEDEC MS-013, DW) and SOIC (D) Packages

APPLICATIONS

- Digital Data or Clock Transmission Over Balanced Transmission Lines

DESCRIPTION

These quad differential drivers are TTL input to pseudo-ECL differential output used for digital data transmission over balanced transmission lines.

The TB5D1M device is a pin and functional replacement for the Agere systems BDG1A and BPNGA quad differential drivers. The TB5D1M has a built-in lightning protection circuit to absorb large transitions on the transmission lines without destroying the device. When the circuit is powered down it loads the transmission line, because of the protection circuit.

The TB5D2H device is a pin and functional replacement for the Agere systems BDG1A and BDGLA quad differential drivers. Upon power down the TB5D2H output circuit appears as an open circuit and does not load the transmission line.

Both drivers feature a 3-state output with a third-state level of less than 0.1 V.

The packaging options available for these quad differential line drivers include a 16-pin SOIC gull-wing (DW) and a 16-pin SOIC (D) package.

Both drivers are characterized for operation from -40°C to 85°C

The logic inputs of this device include internal pull-up resistors of approximately 40 k Ω that are connected to V_{CC} to ensure a logical high level input if the inputs are open circuited.

TB5D1M, TB5D2H

SLLS579B – SEPTEMBER 2003 – REVISED MAY 2004

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

C_{IN} Input capacitance			5		pF

(1) All typical values are at 25°C and with a 3.3-V or 5-V supply.

(2) The input level provides no noise immunity and should be tested only in a static, noise-free environment.

(3) This parameter is listed using a magnitude and polarity/direction convention, rather than an algebraic convention, to match the original Agere data sheet.

(4) Test must be performed one output at a time to prevent damage to the device. No test circuit attached.

THIRD STATE—A TB5D1M (or TB5D2H) driver produces pseudo-ECL levels, and has a third-state mode, which is different than a conventional TTL device. When a TB5D1M (or TB5D2H) driver is placed in the third state, the base of the output transistors is pulled low, bringing the outputs below the active-low level of standard PECL devices. [For example: The TB5D1M low output level is typically 2.7 V, while the third state output level is less than 0.1 V.] In a bidirectional, multipoint, bus application, the driver of one device, which is in its third state, may be back driven by another driver on the bus whose voltage in the low state is lower than the third-stated device. This could come about due to differences in the driver's independent power supplies. In this case, the device in the third state controls the line, thus clamping the line and reducing the signal swing. If the difference voltage between the independent driver power supplies is small, this consideration can be ignored. Again using the TB5D1M driver as an example, a typical supply voltage difference between separate drivers of > 2 V can exist without significantly affecting the amplitude of the signal.

SWITCHING CHARACTERISTICS, 5-V NOMINAL SUPPLY

over recommended operating conditions unless otherwise noted

parameter	test conditions	min	typ ⁽¹⁾	max	unit
t _{p1}	Propagation delay time, input high to output ⁽²⁾		1.2	2	ns
t _{p2}	Propagation delay time, input low to output ⁽²⁾		1.2	2	
Δt _p	Capacitive delay		0.01	0.03	ns/pF
t _{PHZ}	Propagation delay time, high-level-to-high-impedance output		7	12	ns
t _{PLZ}	Propagation delay time, low-level-to-high-impedance output		7	12	
t _{PZH}	Propagation delay time, high-impedance-to-high-level output		5	12	
t _{PZL}	Propagation delay time, high-impedance-to-low-level output		4	12

APPLICATION INFORMATION

Power dissipation

The power dissipation rating, often listed as the package dissipation rating, is a function of the ambient temperature, T_A , and the airflow around the device. This rating correlates with the device's maximum junction temperature, sometimes listed in the absolute maximum ratings tables. The maximum junction temperature accounts for the processes and materials used to fabricate and package the device, in addition to the desired life expectancy.

There are two common approaches to estimating the internal die junction temperature, T_J . In both of these methods, the device's internal power dissipation, P_D , needs to be calculated. This is done by totaling the supply power(s) to arrive at the system power dissipation:

$$\Sigma(V_{Sn} \times I_{Sn}) \quad (1)$$

and then subtracting the total power dissipation of the external load(s):

$$\Sigma(V_{Ln} \times I_{Ln}) \quad (2)$$

The first T_J calculation uses the power dissipation and ambient temperature, along with one parameter: θ_{JA} , the junction-to-ambient thermal resistance, in degrees Celsius per watt.

The product of P_D and θ_{JA} is the junction temperature rise above the ambient temperature. Therefore:

$$T_J = T_A + (P_D \times \theta_{JA}) \quad (3)$$

Figure 14. Thermal Impedance vs Air Flow

Note that θ_{JA} is highly dependent on the PCB on which the device is mounted, and on the airflow over

the device and PCB. JEDEC/EIA has defined standardized test conditions for measuring θ_{JA} . Two commonly used conditions are the low-K and the high-K boards, covered by EIA/JESD51-3 and EIA/JESD51-7 respectively. Figure 14 shows the low-K and high-K values of θ_{JA} versus air flow for this device and its package options.

The standardized θ_{JA} values may not accurately represent the conditions under which the device is used. This can be due to adjacent devices acting as heat sources or heat sinks, to nonuniform airflow, or to the system PCB having significantly different thermal characteristics than the standardized test PCBs. The second method of system thermal analysis is more accurate. This calculation uses the power dissipation and ambient temperature, along with two device and two system-level parameters:

- θ_{JC} , the junction-to-case thermal resistance, in degrees Celsius per watt
- θ_{JB} , the junction-to-board thermal resistance, in degrees Celsius per watt
- θ_{CA} , the case-to-ambient thermal resistance, in degrees Celsius per watt
- θ_{BA} , the board-to-ambient thermal resistance, in degrees Celsius per watt.

In this analysis, there are two parallel paths, one through the case (package) to the ambient, and another through the device to the PCB to the ambient. The system-level junction-to-ambient thermal impedance, $\theta_{JA(S)}$, is the equivalent parallel impedance of the two parallel paths:

$$T_J = T_A + (P_D \times \theta_{JA(S)}) \quad (4)$$

where

$$\theta_{JA(S)} = \frac{(\theta_{JC} + \theta_{CA}) \times (\theta_{JB} + \theta_{BA})}{(\theta_{JC} + \theta_{CA} + \theta_{JB} + \theta_{BA})}$$

The device parameters θ_{JC} and θ_{JB} account for the internal structure of the device. The system-level parameters θ_{CA} and θ_{BA} take into account details of the PCB construction, adjacent electrical and mechanical components, and the environmental conditions including airflow. Finite element (FE), finite difference (FD), or computational fluid dynamics (CFD) programs can determine θ_{CA} and θ_{BA} . Details on using these programs are beyond the scope of this data sheet, but are available from the software manufacturers.

Load Circuits

The test load circuits shown in Figure 3 and Figure 4 are based on a recommended *pi* type of load circuit shown in Figure 15. The 100-Ω differential load resistor R_T at the receiver provide proper termination for the interconnecting transmission line, assuming it has a 100-Ω characteristic impedance. The two resistors R_S to ground at the driver end of the transmission line link provide dc current paths for the emitter follower output transistors. The two resistors to ground normally should not be placed at the receiver end, as they shunt the termination resistor, potentially creating an impedance mismatch with undesirable reflections.

Figure 15. A Recommended *pi* Load Circuit

Another common load circuit, a Y load, is shown in Figure 16. The receiver-end line termination of R_T is provided by the series combination of the two $R_{T/2}$ resistors, while the dc current path to ground is provided by the single resistor R_S . Recommended values, as a function of the nominal supply voltage range, are indicated in the figure.

Figure 16. A Recommended Y Load Circuit

An additional load circuit, similar to one commonly used with ECL and PECL, is shown in Figure 17.

Figure 17. A Recommended PECL-Style Load Circuit

An important feature of all of these recommended load circuits is that they ensure that both of the emitter follower output transistors remain active (conducting current) at all times. When deviating from these recommended values, it is important to make sure that the low-side output transistor does not turn off. Failure to do so increases the t_{skew2} and $V_{OC(PP)}$ values, increasing the potential for electromagnetic radiation.

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - May not be currently available - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

None: Not yet available Lead (Pb-Free).

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Green (RoHS & no Sb/Br): TI defines "Green" to mean "Pb-Free" and in addition, uses package materials that do not contain halogens, including bromine (Br) or antimony (Sb) above 0.1% of total product weight.

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
