

## TSH330

### 1.1 GHz Low-Noise Operational Amplifier

- Bandwidth: 1.1GHz (Gain=+2)
- Quiescent current: 16.6 mA
- Slew rate: 1800V/ $\mu$ s
- Input noise: 1.3nV/ $\sqrt{\text{Hz}}$
- Distortion: SFDR = -78dBc (10MHz, 2Vp-p)
- Output stage optimized for driving 100 $\Omega$  loads
- Tested on 5V power supply

#### Description

The TSH330 is a current feedback operational amplifier using a very high-speed complementary technology to provide a large bandwidth of 1.1GHz in gain of 2 while drawing only 16.6mA of quiescent current. In addition, the TSH330 offers 0.1dB gain flatness up to 160MHz with a gain of 2. With a slew rate of 1800V/ $\mu$ s and an output stage optimized for driving a standard 100 $\Omega$  load, this device is highly suitable for applications where speed and low-distortion are the main requirements.

The TSH330 is a single operator available in the SO8 plastic package, saving board space as well as providing excellent thermal and dynamic performances.

#### Applications

- Communication & video test equipment
- Medical instrumentation
- ADC drivers

#### Order Codes

Part Number	Temperature Range	Package	Conditioning	Marking

## 1 Absolute Maximum Ratings

**Table 1. Key parameters and their absolute maximum ratings**

Symbol	Parameter	Value	Unit
$V_{CC}$	Supply Voltage <sup>1</sup>	6	V
$V_{id}$	Differential Input Voltage <sup>2</sup>	+/-0.5	V
$V_{in}$	Input Voltage Range <sup>3</sup>	+/-2.5	V
$T_{oper}$	Operating Free Air Temperature Range	-40 to + 85	°C
$T_{stg}$	Storage Temperature	-65 to +150	°C
$T_j$	Maximum Junction Temperature	150	°C
$R_{thja}$	SO8 Thermal Resistance Junction to Ambient	60	°C/W
$R_{thjc}$	SO8 Thermal Resistance Junction to Case	28	°C/W
$P_{max}$	SO8 Maximum Power Dissipation <sup>4</sup> (@ $T_a=25^{\circ}C$ ) for $T_j=150^{\circ}C$	830	mW
ESD	HBM: Human Body Model <sup>5</sup> (pins 1, 4, 5, 6, 7 and 8)	2	kV
	HBM: Human Body Model (pins 2 and 3)	0.6	kV
	MM: Machine Model <sup>6</sup> (pins 1, 4, 5, 6, 7 and 8)	200	V
	MM: Machine Model (pins 2 and 3)	80	V
	CDM: Charged Device Model (pins 1, 4, 5, 6, 7 and 8)	1.5	kV
	CDM: Charged Device Model (pins 2 and 3)	1	kV
	Latch-up Immunity	200	mA

1) All voltages values are measured with respect to the ground pin.

2) Differential voltage are non-inverting input terminal with respect to the inverting input terminal.

3) The magnitude of input and output voltage must never exceed  $V_{CC} + 0.3V$ .

4) Short-circuits can cause excessive heating. Destructive dissipation can result from short circuit on amplifiers.

5) Human body model, 100pF discharged through a 1.5kΩ resistor into pMin of device.

6) This is a minimum Value. Machine model ESD, a 200pF cap is charged to the specified voltage, then discharged directly into the IC with no external series resistor (internal resistor < 5Ω), into pin to pin of device.

**Table 2. Operating conditions**

Symbol	Parameter	Value	Unit
$V_{CC}$	Supply Voltage <sup>1</sup>	4.5 to 5.5	V
$V_{icm}$	Common Mode Input Voltage	-Vcc+1.5V, +Vcc-1.5V	V

1) Tested in full production at 5V (±2.5V) supply voltage.

## 2 Electrical Characteristics

Table 3. Electrical characteristics for  $V_{CC} = \pm 2.5\text{Volts}$ ,  $T_{amb} = +25^\circ\text{C}$  (unless otherwise specified)

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
DC performance

### 3 Evaluation Boards

An evaluation board kit optimized for high-speed operational amplifiers is available (order code: KITHSEVAL/STDL). The kit includes the following evaluation boards, as well as a CD-ROM containing datasheets, articles, application notes and a user manual:

- SOT23\_SINGLE\_HF BOARD: Board for the evaluation of a single high-speed op-amp in SOT23-5 package.
- SO8\_SINGLE\_HF: Board for the evaluation of a single high-speed op-amp in SO8 package.
- SO8\_DUAL\_HF: Board for the evaluation of a dual high-speed op-amp in SO8 package.
- SO8\_S\_MULTI: Board for the evaluation of a single high-speed op-amp in SO8 package in inverting and non-inverting configuration, dual and single supply.
- SO14\_TRIPLE: Board for the evaluation of a triple high-speed op-amp in SO14 package with video application considerations.

#### Board material:

- 2 layers
- FR4 ( $\epsilon_r=4.6$ )
- epoxy 1.6mm
- copper thickness: 35 $\mu$ m

Figure 30. Evaluation kit for high-speed op-amps

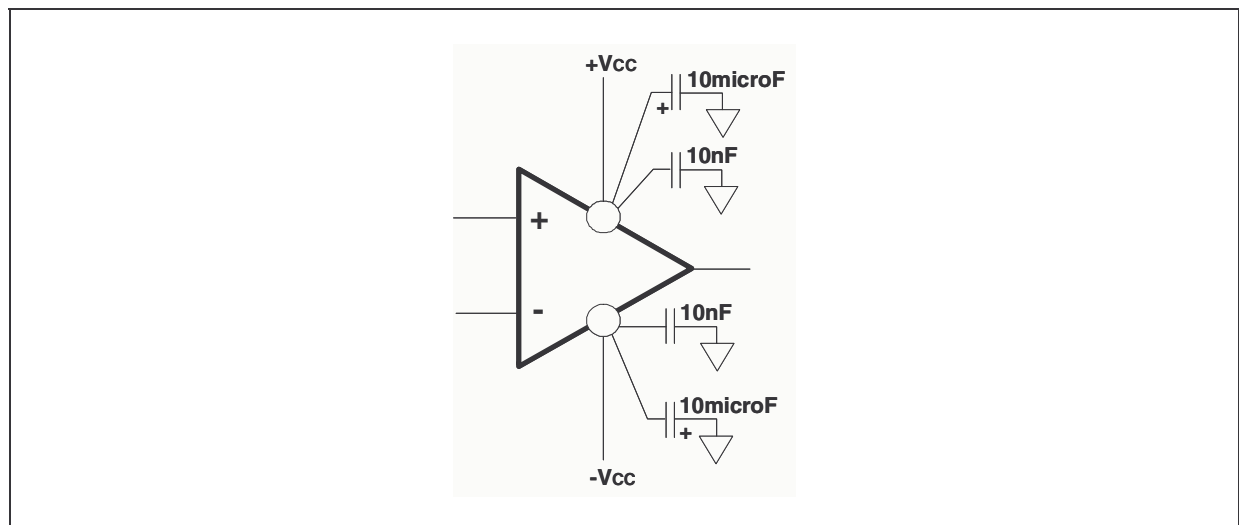

## 4 Power Supply Considerations

Correct power supply bypassing is very important for optimizing performance in high-frequency ranges. Bypass capacitors should be placed as close as possible to the IC pins to improve high-frequency bypassing. A capacitor greater than  $1\mu\text{F}$  is necessary to minimize the distortion. For better quality bypassing, a capacitor of  $10\text{nF}$  can be added using the same implementation conditions. Bypass capacitors must be incorporated for both the negative and the positive supply.

For example, on the SO8\_SINGLE\_HF board, these capacitors are C6, C7, C8, C9.

**Figure 31. Circuit for power supply bypassing**

### Single power supply

In the event that a single supply system is used, new biasing is necessary to assume a positive output dynamic range between  $0\text{V}$  and  $+V_{CC}$  supply rails. Considering the values of  $V_{OH}$  and  $V_{OL}$ , the amplifier will provide an output dynamic from  $+0.9\text{V}$  to  $+4.1\text{V}$  on  $100\Omega$  load.

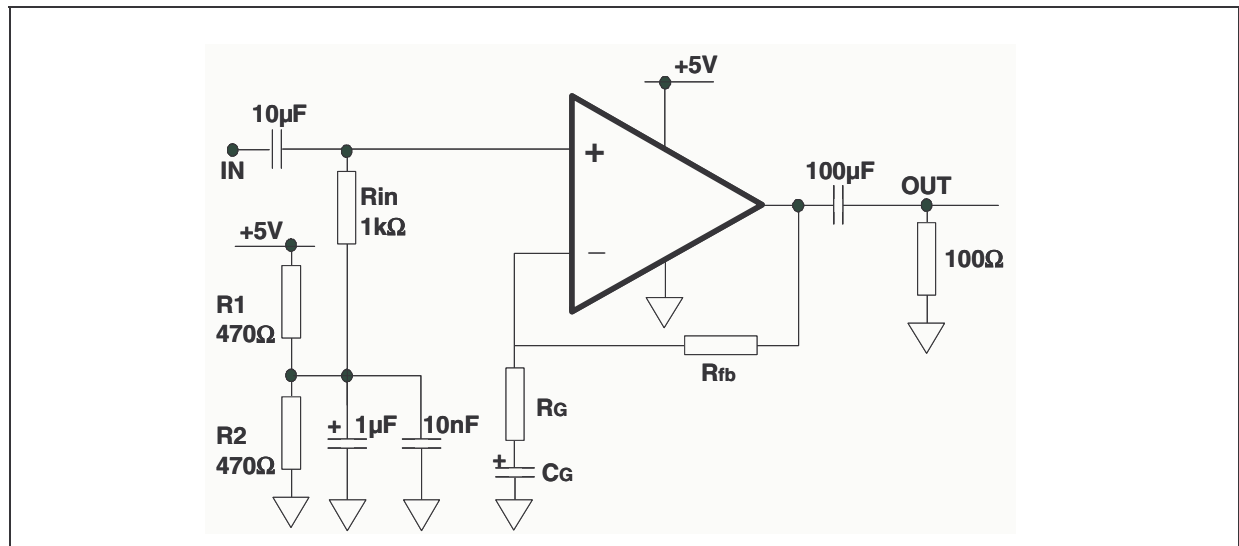

The amplifier must be biased with a mid-supply (nominally  $+V_{CC}/2$ ), in order to maintain the DC component of the signal at this value. Several options are possible to provide this bias supply, such as a virtual ground using an operational amplifier or a two-resistance divider (which is the cheapest solution). A high resistance value is required to limit the current consumption. On the other hand, the current must be high enough to bias the non-inverting input of the amplifier. If we consider this bias current ( $55\mu\text{A}$  max.) as the 1% of the current through the resistance divider to keep a stable mid-supply, two resistances of  $470\Omega$  can be used.

The input provides a high pass filter with a break frequency below  $10\text{Hz}$  which is necessary to remove the original  $0\text{V}$  DC component of the input signal, and to fix it at  $+V_{CC}/2$ .

*Figure 32* illustrates a  $5\text{V}$  single power supply configuration for the SO8\_SINGLE evaluation board (see *Evaluation Boards* on page 10).

A capacitor  $C_G$  is added in the gain network to ensure a unity gain in low-frequency to keep the right DC component at the output.  $C_G$  contributes to a high-pass filter with  $R_{fb}/R_G$  and its value is calculated with a consideration of the cut off frequency of this low-pass filter.

**Figure 32. Circuit for +5V single supply**

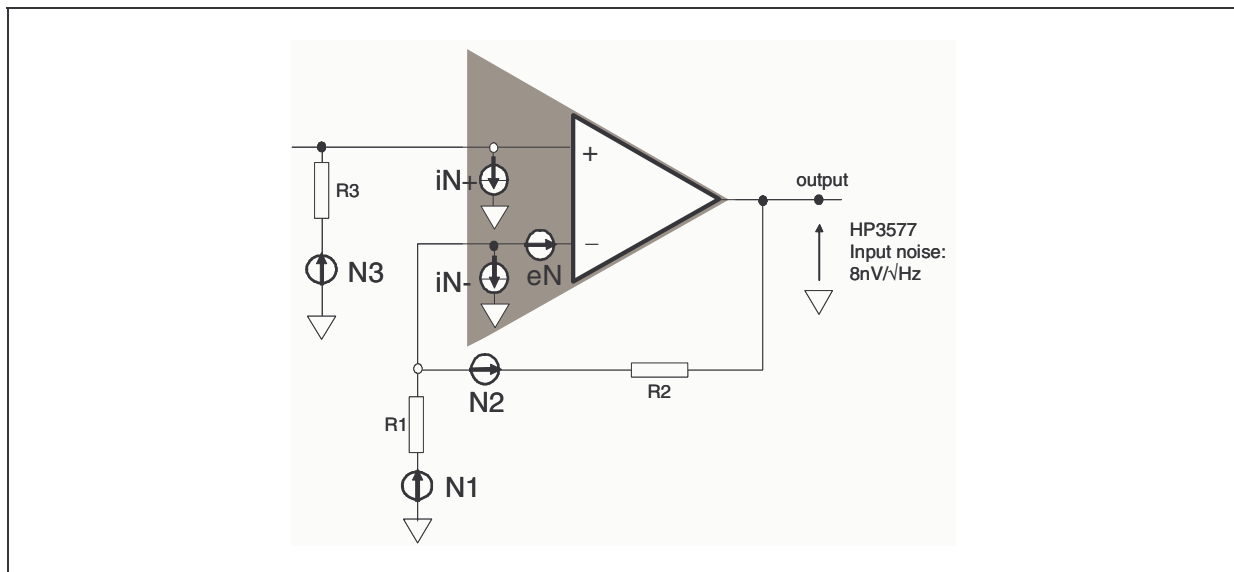

## 5 Noise Measurements

The noise model is shown in *Figure 33*, where:

- $eN$ : input voltage noise of the amplifier
- $iNn$ : negative input current noise of the amplifier
- $iNp$ : positive input current noise of the amplifier

**Figure 33. Noise model**

The thermal noise of a resistance  $R$  is:

$$\sqrt{4kTR\Delta F}$$

where  $\Delta F$  is the specified bandwidth.

On a 1Hz bandwidth the thermal noise is reduced to

$$\sqrt{4kTR}$$

where  $k$  is the Boltzmann's constant, equal to  $1,374.10^{-23} \text{J/}^\circ\text{K}$ .  $T$  is the temperature ( $^\circ\text{K}$ ).

The output noise  $eNo$  is calculated using the Superposition Theorem. However  $eNo$  is not the simple sum of all noise sources, but rather the square root of the sum of the square of each noise source, as shown in *Equation 1*:

$$eNo = \sqrt{V_1^2 + V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2} \quad \text{Equation 1}$$

$$eNo^2 = eN^2 \times g^2 + iNn^2 \times R_2^2 + iNp^2 \times R_3^2 \times g^2 + \frac{R_2^2}{R_1} \times 4kTR_1 + 4kTR_2 + 1 + \frac{R_2^2}{R_1} \times 4kTR_3 \quad \text{Equation 2}$$

The input noise of the instrumentation must be extracted from the measured noise value. The real output noise value of the driver is:

$$eNo = \sqrt{(\text{Measured})^2 - (\text{instrumentation})^2} \quad \text{Equation 3}$$

The input noise is called the Equivalent Input Noise as it is not directly measured but is evaluated from the measurement of the output divided by the closed loop gain ( $eNo/g$ ).

After simplification of the fourth and the fifth term of [Equation 2](#) we obtain:

$$eNo^2 = eN^2 \times g^2 + iNn^2 \times R2^2 + iNp^2 \times R3^2 \times g^2 + g \times 4kTR2 + 1 + \frac{R2^2}{R1} \times 4kTR3 \quad \text{Equation 4}$$

### Measurement of the Input Voltage Noise $eN$

If we assume a short-circuit on the non-inverting input ( $R3=0$ ), from [Equation 4](#) we can derive:

$$eNo = \sqrt{eN^2 \times g^2 + iNn^2 \times R2^2 + g \times 4kTR2} \quad \text{Equation 5}$$

In order to easily extract the value of  $eN$ , the resistance  $R2$  will be chosen to be as low as possible. In the other hand, the gain must be large enough:

$$R3=0, \text{ gain: } g=100$$

### Measurement of the Negative Input Current Noise $iNn$

To measure the negative input current noise  $iNn$ , we set  $R3=0$  and use [Equation 5](#). This time the gain must be lower in order to decrease the thermal noise contribution:

$$R3=0, \text{ gain: } g=10$$

### Measurement of the Positive Input Current Noise $iNp$

To extract  $iNp$  from [Equation 3](#), a resistance  $R3$  is connected to the non-inverting input. The value of  $R3$  must be chosen in order to keep its thermal noise contribution as low as possible against the  $iNp$  contribution:

$$R3=100W, \text{ gain: } g=10$$

## 6 Intermodulation Distortion Product

The non-ideal output of the amplifier can be described by the following series:

$$V_{out} = C_0 + C_1 V_{in} + C_2 V_{in}^2 + \dots + C_n V_{in}^n$$

due to non-linearity in the input-output amplitude transfer, where the input is  $V_{in} = A \sin \omega t$ ,  $C_0$  is the DC component,  $C_1(V_{in})$  is the fundamental and  $C_n$  is the amplitude of the harmonics of the output signal  $V_{out}$ .

A one-frequency (one-tone) input signal contributes to harmonic distortion. A two-tone input signal contributes to harmonic distortion and to the intermodulation product.

The study of the intermodulation and distortion for a two-tone input signal is the first step in characterizing the driving capability of multi-tone input signals.

In this case:

$$V_{in} = A \sin \omega_1 t + A \sin \omega_2 t$$

then:

$$V_{out} = C_0 + C_1 (A \sin \omega_1 t + A \sin \omega_2 t) + C_2 (A \sin \omega_1 t + A \sin \omega_2 t)^2 + \dots + C_n (A \sin \omega_1 t + A \sin \omega_2 t)^n$$

From this expression, we can extract the distortion terms, and the intermodulation terms form a single sine wave: second-order intermodulation terms IM2 by the frequencies  $(\omega_1 - \omega_2)$  and  $(\omega_1 + \omega_2)$  with an amplitude of  $C_2 A^2$  and third-order intermodulation terms IM3 by the frequencies  $(2\omega_1 - \omega_2)$ ,  $(2\omega_1 + \omega_2)$ ,  $(-\omega_1 + 2\omega_2)$  and  $(\omega_1 + 2\omega_2)$  with an amplitude of  $(3/4)C_3 A^3$ .

The measurement of the intermodulation product of the driver is achieved by using the driver as a mixer by a summing amplifier configuration (see [Figure 34](#)). In this way, the non-linearity problem of an external mixing device is avoided.

**Figure 34. Inverting summing amplifier (using evaluation board SO8\_S\_MULTI)**

## 7 The Bias of an Inverting Amplifier

A resistance is necessary to achieve a good input biasing, such as resistance R shown in [Figure 35](#).

The magnitude of this resistance is calculated by assuming the negative and positive input bias current. The aim is to compensate for the offset bias current, which could affect the input offset voltage and the output DC component. Assuming  $I_{b-}$ ,  $I_{b+}$ ,  $R_{in}$ ,  $R_{fb}$  and a zero volt output, the resistance R will be:

$$R = \frac{R_{in} \times R_{fb}}{R_{in} + R_{fb}}$$

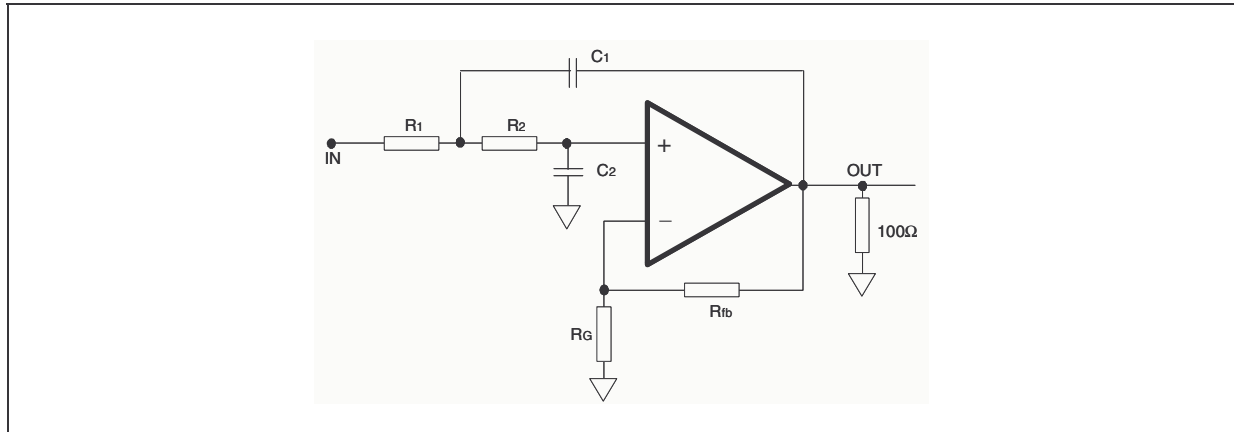

Figure 35. Compensation of the input bias current

## 8 Active Filtering

Figure 36. Low-pass active filtering, Sallen-Key

From the resistors  $R_{fb}$  and  $R_G$  we can directly calculate the gain of the filter in a classical non-inverting amplification configuration:

$$A_V = g = 1 + \frac{R_{fb}}{R_g}$$

We assume the following expression as the response of the system:

$$T_{j\omega} = \frac{V_{out_{j\omega}}}{V_{in_{j\omega}}} = \frac{g}{1 + 2\zeta \frac{j\omega}{\omega_c} + \frac{(j\omega)^2}{\omega_c^2}}$$

The cut-off frequency is not gain-dependent and so becomes:

$$\omega_c = \frac{1}{\sqrt{R_1 R_2 C_1 C_2}}$$

The damping factor is calculated by the following expression:

$$\zeta = \frac{1}{2} \omega_c (C_1 R_1 + C_1 R_2 + C_2 R_1 - C_1 R_1 g)$$

The higher the gain, the more sensitive the damping factor is. When the gain is higher than 1, it is preferable to use some very stable resistor and capacitor values. In the case of  $R_1 = R_2 = R$ :

$$\zeta = \frac{2C_2 - C_1 \frac{R_{fb}}{R_g}}{2\sqrt{C_1 C_2}}$$

Due to a limited selection of values of capacitors in comparison with resistors, we can fix  $C_1 = C_2 = C$ , so that:

$$\zeta = \frac{2R_2 - R_1 \frac{R_{fb}}{R_g}}{2\sqrt{R_1 R_2}}$$
