

# LM2576

## Advance Information

# Easy Switcher™ 3.0 A Step-Down Voltage Regulator

The LM2576 series of regulators are monolithic integrated circuits ideally suited for easy and convenient design of a step-down switching regulator (buck converter). All circuits of this series are capable of driving a 3.0 A load with excellent line and load regulation. These devices are available in fixed output voltages of 3.3 V, 5.0 V, 12 V, 15 V, and an adjustable output version.

These regulators were designed to minimize the number of external components to simplify the power supply design. Standard series of inductors optimized for use with the LM2576 are offered by several different inductor manufacturers.

Since the LM2576 converter is a switch-mode power supply, its efficiency is significantly higher in comparison with popular three-terminal linear regulators, especially with higher input voltages. In many cases, the power dissipated is so low that no heatsink is required or its size could be reduced dramatically.

A standard series of inductors optimized for use with the LM2576 are available from several different manufacturers. This feature greatly simplifies the design of switch-mode power supplies.

The LM2576 features include a guaranteed  $\pm 4\%$  tolerance on output voltage within specified input voltages and output load conditions, and  $\pm 10\%$  on the oscillator frequency ( $\pm 2\%$  over  $0^\circ\text{C}$  to  $125^\circ\text{C}$ ). External shutdown is included, featuring 80  $\mu\text{A}$  (typical) standby current. The output switch includes cycle-by-cycle current limiting, as well as thermal shutdown for full protection under fault conditions.

### Features

- 3.3 V, 5.0 V, 12 V, 15 V, and Adjustable Output Versions
- Adjustable Version Output Voltage Range, 1.23 V to 37 V  $\pm 4\%$  Maximum Over Line and Load Conditions
- Guaranteed 3.0 A Output Current
- Wide Input Voltage Range
- Requires Only 4 External Components
- 52 kHz Fixed Frequency Internal Oscillator
- TTL Shutdown Capability, Low Power Standby Mode
- High Efficiency
- Uses Readily Available Standard Inductors
- Thermal Shutdown and Current Limit Protection

### Applications

- Simple High-Efficiency Step-Down (Buck) Regulator
- Efficient Pre-Regulator for Linear Regulators
- On-Card Switching Regulators
- Positive to Negative Converter (Buck-Boost)
- Negative Step-Up Converters
- Power Supply for Battery Chargers

**NOTES:** 3. The oscillator frequency reduces to approximately 18 kHz in the event of an output short or an overload which causes the regulated output voltage to drop approximately 40% from the nominal output voltage. This self protection feature lowers the average dissipation of the IC by lowering the minimum duty cycle from 5% down to approximately 2%.

4. Output (Pin 2) sourcing current. No diode, inductor or capacitor connected to output pin.

5. Feedback (Pin 4) removed from output and connected to 0 V.

6. Feedback (Pin 4) removed from output and connected to +12 V for the Adjustable, 3.3 V, and 5.0 V versions, and +25 V for the 12 V and 15 V versions, to force the output transistor "off".

7.  $V_{in} = 40\text{ V}$ .

between 1.0 k and 5.0 k

## PCB LAYOUT GUIDELINES

As in any switching regulator, the layout of the printed circuit board is very important. Rapidly switching currents associated with wiring inductance, stray capacitance and parasitic inductance of the printed circuit board traces can generate voltage transients which can generate electromagnetic interferences (EMI) and affect the desired operation. As indicated in the Figure 15, to minimize inductance and ground loops, the length of the leads indicated by heavy lines should be kept as short as possible.

For best results, single-point grounding (as indicated) or ground plane construction should be used.

On the other hand, the PCB area connected to the Pin 2 (emitter of the internal switch) of the LM2576 should be kept to a minimum in order to minimize coupling to sensitive circuitry.

Another sensitive part of the circuit is the feedback. It is important to keep the sensitive feedback wiring short. To assure this, physically locate the programming resistors near to the regulator, when using the adjustable version of the LM2576 regulator.

# LM2576

## PIN FUNCTION DESCRIPTION

Pin	Symbol	Description (Refer to Figure 1)
1	$V_{in}$	This pin is the positive input supply for the LM2576 step-down switching regulator. In order to minimize voltage transients and to supply the switching currents needed by the regulator, a suitable input bypass capacitor must be present ( $C_{in}$ in Figure 1).
2	Output	This is the emitter of the internal switch. The saturation voltage $V_{sat}$ of this output switch is typically 1.5 V. It should be kept in mind that the PCB area connected to this pin should be kept to a minimum in order to minimize coupling to sensitive circuitry.
3	Gnd	Circuit ground pin. See the information about the printed circuit board layout.
4	Feedback	This pin senses regulated output voltage to complete the feedback loop. The signal is divided by the internal resistor divider network R2, R1 and applied to the non-inverting input of the internal error amplifier. In the Adjustable version of the LM2576 switching regulator this pin is the direct input of the error amplifier and the resistor network R2, R1 is connected externally to allow programming of the output voltage.
5	ON/OFF	It allows the switching regulator circuit to be shut down using logic level signals, thus dropping the total input supply current to approximately 80 $\mu$ A. The threshold voltage is typically 1.4 V. Applying a voltage above this value (up to $+V_{in}$ ) shuts the regulator off. If the voltage applied to this pin is lower than 1.4 V or if this pin is left open, the regulator will be in the "on" condition.

## DESIGN PROCEDURE

### Buck Converter Basics

The LM2576 is a "Buck" or Step-Down Converter which is the most elementary forward-mode converter. Its basic schematic can be seen in Figure 16.

The operation of this regulator topology has two distinct time periods. The first one occurs when the series switch is on, the input voltage is connected to the input of the inductor.

The output of the inductor is the output voltage, and the rectifier (or catch diode) is reverse biased. During this period, since there is a constant voltage source connected across the inductor, the inductor current begins to linearly ramp upwards, as described by the following equation:

$$I_{L(on)} = \frac{(V_{in} - V_{out}) t_{on}}{L}$$

During this "on" period, energy is stored within the core material in the form of magnetic flux. If the inductor is properly designed, there is sufficient energy stored to carry the requirements of the load during the "off" period.

Figure 16. Basic Buck Converter

The next period is the "off" period of the power switch. When the power switch turns off, the voltage across the inductor reverses its polarity and is clamped at one diode voltage drop below ground by the catch diode. The current now flows through the catch diode thus maintaining the load current loop. This removes the stored energy from the inductor. The inductor current during this time is:

$$I_{L(off)} = \frac{(V_{out} - V_D) t_{off}}{L}$$

This period ends when the power switch is once again turned on. Regulation of the converter is accomplished by varying the duty cycle of the power switch. It is possible to describe the duty cycle as follows:

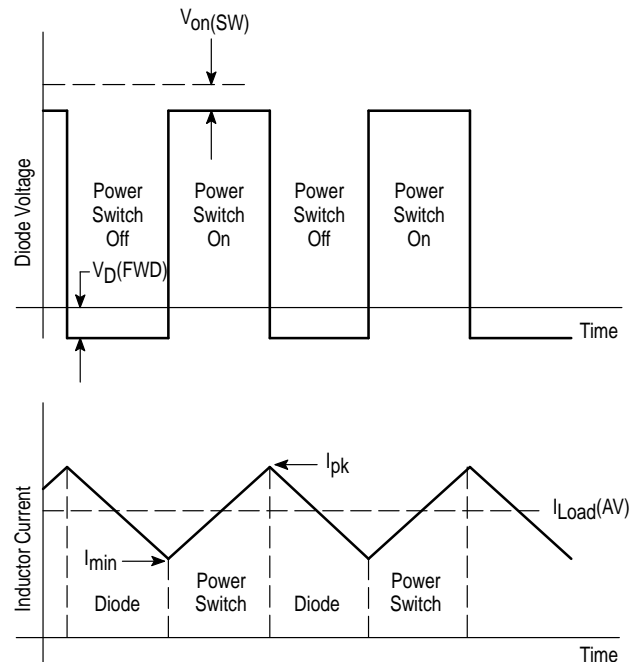

$$d = \frac{t_{on}}{T}, \text{ where } T \text{ is the period of switching.}$$

For the buck converter with ideal components, the duty cycle can also be described as:

$$d = \frac{V_{out}}{V_{in}}$$

Figure 17 shows the buck converter, idealized waveforms of the catch diode voltage and the inductor current.

Figure 17. Buck Converter Idealized Waveforms

## LM2576

**Procedure (Fixed Output Voltage Version)** In order to simplify the switching regulator design, a step-by-step design procedure and some examples are provided.

Procedure	Example
<p><b>Given Parameters:</b>  <math>V_{out}</math> = Regulated Output Voltage (3.3 V, 5.0 V, 12 V or 15 V)  <math>V_{in(max)}</math> = Maximum Input Voltage  <math>I_{Load(max)}</math> = Maximum Load Current</p>	<p><b>Given Parameters:</b>  <math>V_{out}</math> = 5.0 V  <math>V_{in(max)}</math> = 15 V  <math>I_{Load(max)}</math> = 3.0 A</p>
<p><b>1. Controller IC Selection</b>            According to the required input voltage, output voltage and current, select the appropriate type of the controller IC output voltage version.</p>	<p><b>1. Controller IC Selection</b>            According to the required input voltage, output voltage, current polarity and current value, use the LM2576-5 controller IC</p>
<p><b>2. Input Capacitor Selection (<math>C_{in}</math>)</b>            To prevent large voltage transients from appearing at the input and for stable operation of the converter, an aluminium or tantalum electrolytic bypass capacitor is needed between the input pin +<math>V_{in}</math> and ground pin Gnd. This capacitor should be located close to the IC using short leads. This capacitor should have a low ESR (Equivalent Series Resistance) value.</p>	<p><b>2. Input Capacitor Selection (<math>C_{in}</math>)</b>            A 100 <math>\mu</math>F, 25 V aluminium electrolytic capacitor located near to the input and ground pins provides sufficient bypassing.</p>
<p><b>3. Catch Diode Selection (D1)</b>  <b>A.</b> Since the diode maximum peak current exceeds the regulator maximum load current the catch diode current rating must be at least 1.2 times greater than the maximum load current. For a robust design the diode should have a current rating equal to the maximum current limit of the LM2576 to be able to withstand a continuous output short  <b>B.</b> The reverse voltage rating of the diode should be at least 1.25 times the maximum input voltage.</p>	<p><b>3. Catch Diode Selection (D1)</b>  <b>A.</b> For this example the current rating of the diode is 3.0 A.   <b>B.</b> Use a 20 V 1N5820 Schottky diode, or any of the suggested fast recovery diodes shown in Table 1.</p>
<p><b>4. Inductor Selection (L1)</b>  <b>A.</b> According to the required working conditions, select the correct inductor value using the selection guide from Figures 18 to 22.  <b>B.</b> From the appropriate inductor selection guide, identify the inductance region intersected by the Maximum Input Voltage line and the Maximum Load Current line. Each region is identified by an inductance value and an inductor code.  <b>C.</b> Select an appropriate inductor from the several different manufacturers part numbers listed in Table 2.            The designer must realize that the inductor current rating must be higher than the maximum peak current flowing through the inductor. This maximum peak current can be calculated as follows:</p> $I_{p(max)} = I_{Load(max)} + \frac{(V_{in} - V_{out}) t_{on}}{2L}$ <p>where <math>t_{on}</math> is the "on" time of the power switch and</p> $t_{on} = \frac{V_{out}}{V_{in}} \times \frac{1.0}{f_{osc}}$ <p>For additional information about the inductor, see the inductor section in the "Application Hints" section of this data sheet.</p>	<p><b>4. Inductor Selection (L1)</b>  <b>A.</b> Use the inductor selection guide shown in Figures 19.   <b>B.</b> From the selection guide, the inductance area intersected by the 15 V line and 3.0 A line is L100.   <b>C.</b> Inductor value required is 100 <math>\mu</math>H. From Table 2, choose an inductor from any of the listed manufacturers.</p>

## LM2576

**Procedure (Fixed Output Voltage Version) (continued)** In order to simplify the switching regulator design, a step-by-step design procedure and some examples are provided.

Procedure	Example
<p><b>5. Output Capacitor Selection (<math>C_{out}</math>)</b></p> <p><b>A.</b> Since the LM2576 is a forward-mode switching regulator with voltage mode control, its open loop 2-pole-1-zero frequency characteristic has the dominant pole-pair determined by the output capacitor and inductor values. For stable operation and an acceptable ripple voltage, (approximately 1% of the output voltage) a value between 680 <math>\mu</math>F and 2000 <math>\mu</math>F is recommended.</p> <p><b>B.</b> Due to the fact that the higher voltage electrolytic capacitors generally have lower ESR (Equivalent Series Resistance) numbers, the output capacitor's voltage rating should be at least 1.5 times greater than the output voltage. For a 5.0 V regulator, a rating at least 8.0 V is appropriate, and a 10 V or 16 V rating is recommended.</p>	<p><b>5. Output Capacitor Selection (<math>C_{out}</math>)</b></p> <p><b>A.</b> <math>C_{out}</math> = 680 <math>\mu</math>F to 2000 <math>\mu</math>F standard aluminium electrolytic.</p> <p><b>B.</b> Capacitor voltage rating = 20 V.</p>

### Procedure (Adjustable Output Version: LM2576-ADJ)

Procedure	Example
<p><b>Given Parameters:</b></p> <p><math>V_{out}</math> = Regulated Output Voltage  <math>V_{in(max)}</math> = Maximum DC Input Voltage  <math>I_{Load(max)}</math> = Maximum Load Current</p>	<p><b>Given Parameters:</b></p> <p><math>V_{out}</math> = 8.0 V  <math>V_{in(max)}</math> = 25 V  <math>I_{Load(max)}</math> = 2.5 A</p>
<p><b>1. Programming Output Voltage</b></p> <p>To select the right programming resistor R1 and R2 value (see Figure 2) use the following formula:</p> $V_{out} = V_{ref} \left( 1.0 + \frac{R2}{R1} \right) \text{ where } V_{ref} = 1.23 \text{ V}$ <p>Resistor R1 can be between 1.0 k and 5.0 k<math>\Omega</math>. (For best temperature coefficient and stability with time, use 1% metal film resistors).</p> $R2 = R1 \left( \frac{V_{out}}{V_{ref}} - 1.0 \right)$	<p><b>1. Programming Output Voltage</b> (selecting R1 and R2)</p> <p>Select R1 and R2:</p> $V_{out} = 1.23 \left( 1.0 + \frac{R2}{R1} \right) \text{ Select } R1 = 1.8 \text{ k}\Omega$ $R2 = R1 \left( \frac{V_{out}}{V_{ref}} - 1.0 \right) = 1.8 \text{ k} \left( \frac{8.0 \text{ V}}{1.23 \text{ V}} - 1.0 \right)$ <p><math>R2 = 9.91 \text{ k}\Omega</math>, choose a 9.88 k metal film resistor.</p>
<p><b>2. Input Capacitor Selection (<math>C_{in}</math>)</b></p> <p>To prevent large voltage transients from appearing at the input and for stable operation of the converter, an aluminium or tantalum electrolytic bypass capacitor is needed between the input pin +<math>V_{in}</math> and ground pin Gnd. This capacitor should be located close to the IC using short leads. This capacitor should have a low ESR (Equivalent Series Resistance) value.</p> <p>For additional information see input capacitor section in the "Application Hints" section of this data sheet.</p>	<p><b>2. Input Capacitor Selection (<math>C_{in}</math>)</b></p> <p>A 100 <math>\mu</math>F, 150 V aluminium electrolytic capacitor located near the input and ground pin provides sufficient bypassing.</p>
<p><b>3. Catch Diode Selection (D1)</b></p> <p><b>A.</b> Since the diode maximum peak current exceeds the regulator maximum load current the catch diode current rating must be at least 1.2 times greater than the maximum load current. For a robust design, the diode should have a current rating equal to the maximum current limit of the LM2576 to be able to withstand a continuous output short.</p> <p><b>B.</b> The reverse voltage rating of the diode should be at least 1.25 times the maximum input voltage.</p>	<p><b>3. Catch Diode Selection (D1)</b></p> <p><b>A.</b> For this example, a 3.0 A current rating is adequate.</p> <p><b>B.</b> Use a 30 V 1N5821 Schottky diode or any suggested fast recovery diode in the Table 1.</p>

Procedure (Adjustable Output Version: LM2576-ADJ) (continued)

Procedure	Example
<p><b>4. Inductor Selection (L1)</b></p> <p>A. Use the following formula to calculate the inductor Volt x microsecond [V x μs] constant:</p> $E \times T = (V_{in} - V_{out}) \frac{V_{out}}{V_{in}} \times \frac{10^6}{F[\text{Hz}]} \text{ [V} \times \mu\text{s]}$ <p>B. Match the calculated E x T value with the corresponding number on the vertical axis of the Inductor Value Selection Guide shown in Figure 22. This E x T constant is a measure of the energy handling capability of an inductor and is dependent upon the type of core, the core area, the number of turns, and the duty cycle.</p> <p>C. Next step is to identify the inductance region intersected by the E x T value and the maximum load current value on the horizontal axis shown in Figure 25.</p> <p>D. From the inductor code, identify the inductor value. Then select an appropriate inductor from Table 2. The inductor chosen must be rated for a switching frequency of 52 kHz and for a current rating of 1.15 x I<sub>Load</sub>. The inductor current rating can also be determined by calculating the inductor peak current:</p> $I_{p(\text{max})} = I_{\text{Load}(\text{max})} + \frac{(V_{in} - V_{out}) t_{\text{on}}}{2L}$ <p>where t<sub>on</sub> is the "on" time of the power switch and</p> $t_{\text{on}} = \frac{V_{\text{out}}}{V_{in}} \times \frac{1.0}{f_{\text{osc}}}$ <p>For additional information about the inductor, see the inductor section in the "External Components" section of this data sheet.</p>	<p><b>4. Inductor Selection (L1)</b></p> <p>A. Calculate E x T [V x μs] constant:</p> $E \times T = (25 - 8.0) \times \frac{8.0}{25} \times \frac{1000}{52} = 80 \text{ [V} \times \mu\text{s]}$ <p>B. E x T = 80 [V x μs]</p> <p>C. I<sub>Load(max)</sub> = 2.5 A Inductance Region = H150</p> <p>D. Proper inductor value = 150 μH Choose the inductor from Table 2.</p>
<p><b>5. Output Capacitor Selection (C<sub>out</sub>)</b></p> <p>A. Since the LM2576 is a forward-mode switching regulator with voltage mode control, its open loop 2-pole-1-zero frequency characteristic has the dominant pole-pair determined by the output capacitor and inductor values. For stable operation, the capacitor must satisfy the following requirement:</p> $C_{\text{out}} \geq 13,300 \frac{V_{in(\text{max})}}{V_{\text{out}} \times L [\mu\text{H}]} \text{ [}\mu\text{F]}$ <p>B. Capacitor values between 10 μF and 2000 μF will satisfy the loop requirements for stable operation. To achieve an acceptable output ripple voltage and transient response, the output capacitor may need to be several times larger than the above formula yields.</p> <p>C. Due to the fact that the higher voltage electrolytic capacitors generally have lower ESR (Equivalent Series Resistance) numbers, the output capacitor's voltage rating should be at least 1.5 times greater than the output voltage. For a 5.0 V regulator, a rating of at least 8.0 V is appropriate, and a 10 V or 16 V rating is recommended.</p>	<p><b>5. Output Capacitor Selection (C<sub>out</sub>)</b></p> <p>A.</p> $C_{\text{out}} \geq 13,300 \times \frac{25}{8 \times 150} = 332.5 \mu\text{F}$ <p>To achieve an acceptable ripple voltage, select C<sub>out</sub> = 680 μF electrolytic capacitor.</p>

## EXTERNAL COMPONENTS

### Input Capacitor ( $C_{in}$ )

#### *The Input Capacitor Should Have a Low ESR*

For stable operation of the switch mode converter a low ESR (Equivalent Series Resistance) aluminium or solid tantalum bypass capacitor is needed between the input pin and the ground pin, to prevent large voltage transients from appearing at the input. It must be located near the regulator and use short leads. With most electrolytic capacitors, the capacitance value decreases and the ESR increases with lower temperatures. For reliable operation in temperatures below  $-25^{\circ}\text{C}$  larger values of the input capacitor may be needed. Also paralleling a ceramic or solid tantalum capacitor will increase the regulator stability at cold temperatures.

#### *RMS Current Rating of $C_{in}$*

The important parameter of the input capacitor is the RMS current rating. Capacitors that are physically large and have large surface area will typically have higher RMS current ratings. For a given capacitor value, a higher voltage electrolytic capacitor will be physically larger than a lower voltage capacitor, and thus be able to dissipate more heat to the surrounding air, and therefore will have a higher RMS current rating. The consequence of operating an electrolytic capacitor beyond the RMS current rating is a shortened operating life. In order to assure maximum capacitor operating lifetime, the capacitor's RMS ripple current rating should be:

$$I_{rms} > 1.2 \times d \times I_{Load}$$

where  $d$  is the duty cycle, for a buck regulator

$$d = \frac{t_{on}}{T} = \frac{V_{out}}{V_{in}}$$

and  $d = \frac{t_{on}}{T} = \frac{|V_{out}|}{|V_{out}| + V_{in}}$  for a buck-boost regulator.

### Output Capacitor ( $C_{out}$ )

For low output ripple voltage and good stability, low ESR output capacitors are recommended. An output capacitor has two main functions: it filters the output and provides regulator loop stability. The ESR of the output capacitor and the peak-to-peak value of the inductor ripple current are the main factors contributing to the output ripple voltage value. Standard aluminium electrolytics could be adequate for some applications but for quality design, low ESR types are recommended.

An aluminium electrolytic capacitor's ESR value is related to many factors such as the capacitance value, the voltage rating, the physical size and the type of construction. In most cases, the higher voltage electrolytic capacitors have lower ESR value. Often capacitors with much higher voltage ratings may be needed to provide low ESR values that, are required for low output ripple voltage.

#### *The Output Capacitor Requires an ESR Value That Has an Upper and Lower Limit*

As mentioned above, a low ESR value is needed for low output ripple voltage, typically 1% to 2% of the output voltage. But if the selected capacitor's ESR is extremely low (below  $0.05 \Omega$ ), there is a possibility of an unstable feedback loop, resulting in oscillation at the output. This situation can occur when a tantalum capacitor, that can have a very low ESR, is used as the only output capacitor.

#### *At Low Temperatures, Put in Parallel Aluminium Electrolytic Capacitors with Tantalum Capacitors*

Electrolytic capacitors are not recommended for temperatures below  $-25^{\circ}\text{C}$ . The ESR rises dramatically at cold temperatures and typically rises 3 times at  $-25^{\circ}\text{C}$  and as much as 10 times at  $-40^{\circ}\text{C}$ . Solid tantalum capacitors have much better ESR spec at cold temperatures and are recommended for temperatures below  $-25^{\circ}\text{C}$ . They can be also used in parallel with aluminium electrolytics. The value of the tantalum capacitor should be about 10% or 20% of the total capacitance. The output capacitor should have at least 50% higher RMS ripple current rating at 52 kHz than the peak-to-peak inductor ripple current.

### Catch Diode

#### *Locate the Catch Diode Close to the LM2576*

The LM2576 is a step-down buck converter; it requires a fast diode to provide a return path for the inductor current when the switch turns off. This diode must be located close to the LM2576 using short leads and short printed circuit traces to avoid EMI problems.

#### *Use a Schottky or a Soft Switching Ultra-Fast Recovery Diode*

Since the rectifier diodes are very significant sources of losses within switching power supplies, choosing the rectifier that best fits into the converter design is an important process. Schottky diodes provide the best performance

## LM2576

because of their fast switching speed and low forward voltage drop.

They provide the best efficiency especially in low output voltage applications (5.0 V and lower). Another choice could be Fast-Recovery, or Ultra-Fast Recovery diodes. It has to be noted, that some types of these diodes with an abrupt turnoff characteristic may cause instability or EMI troubles.

A fast-recovery diode with soft recovery characteristics can better fulfill some quality, low noise design requirements. Table 1 provides a list of suitable diodes for the LM2576 regulator. Standard 50/60 Hz rectifier diodes, such as the 1N4001 series or 1N5400 series are **NOT** suitable.

### Inductor

The magnetic components are the cornerstone of all switching power supply designs. The style of the core and the winding technique used in the magnetic component's design has a great influence on the reliability of the overall power supply.

Using an improper or poorly designed inductor can cause high voltage spikes generated by the rate of transitions in current within the switching power supply, and the possibility of core saturation can arise during an abnormal operational mode. Voltage spikes can cause the semiconductors to enter avalanche breakdown and the part can instantly fail if enough energy is applied. It can also cause significant RFI (Radio Frequency Interference) and EMI (Electro-Magnetic Interference) problems.

### Continuous and Discontinuous Mode of Operation

The LM2576 step-down converter can operate in both the continuous and the discontinuous modes of operation. The regulator works in the continuous mode when loads are relatively heavy, the current flows through the inductor continuously and never falls to zero. Under light load conditions, the circuit will be forced to the discontinuous mode when inductor current falls to zero for certain period of time (see Figure 23 and Figure 24). Each mode has distinctively different operating characteristics, which can affect the regulator performance and requirements. In many cases the preferred mode of operation is the continuous mode. It offers greater output power, lower peak currents in the switch, inductor and diode, and can have a lower output ripple voltage. On the other hand it does require larger inductor values to keep the inductor current flowing continuously, especially at low output load currents and/or high input voltages.

To simplify the inductor selection process, an inductor selection guide for the LM2576 regulator was added to this data sheet (Figures 18 through 22). This guide assumes that the regulator is operating in the continuous mode, and selects an inductor that will allow a peak-to-peak inductor ripple current to be a certain percentage of the maximum design load current. This percentage is allowed to change as

different design load currents are selected. For light loads (less than approximately 300 mA) it may be desirable to operate the regulator in the discontinuous mode, because the inductor value and size can be kept relatively low. Consequently, the percentage of inductor peak-to-peak current increases. This discontinuous mode of operation is perfectly acceptable for this type of switching converter. Any buck regulator will be forced to enter discontinuous mode if the load current is light enough.

**Figure 23. Continuous Mode Switching Current Waveforms**

### Selecting the Right Inductor Style

Some important considerations when selecting a core type are core material, cost, the output power of the power supply, the physical volume the inductor must fit within, and the amount of EMI (Electro-Magnetic Interference) shielding that the core must provide. The inductor selection guide covers different styles of inductors, such as pot core, E-core, toroid and bobbin core, as well as different core materials such as ferrites and powdered iron from different manufacturers.

For high quality design regulators the toroid core seems to be the best choice. Since the magnetic flux is contained within the core, it generates less EMI, reducing noise problems in sensitive circuits. The least expensive is the bobbin core type, which consists of wire wound on a ferrite rod core. This type of inductor generates more EMI due to the fact that its core is open, and the magnetic flux is not contained within the core.

When multiple switching regulators are located on the same printed circuit board, open core magnetics can cause interference between two or more of the regulator circuits, especially at high currents due to mutual coupling. A toroid, pot core or E-core (closed magnetic structure) should be used in such applications.

### Do Not Operate an Inductor Beyond its Maximum Rated Current

Exceeding an inductor's maximum current rating may cause the inductor to overheat because of the copper wire losses, or the core may saturate. Core saturation occurs when the flux density is too high and consequently the cross sectional area of the core can no longer support additional lines of magnetic flux.

This causes the permeability of the core to drop, the inductance value decreases rapidly and the inductor begins to look mainly resistive. It has only the DC resistance of the winding. This can cause the switch current to rise very rapidly and force the LM2576 internal switch into cycle-by-cycle current limit, thus reducing the DC output load current. This can also result in overheating of the inductor and/or the LM2576. Different inductor types have different saturation characteristics, and this should be kept in mind when selecting an inductor.

Figure 24. Discontinuous Mode Switching Current Waveforms

## GENERAL RECOMMENDATIONS

### Output Voltage Ripple and Transients

#### Source of the Output Ripple

Since the LM2576 is a switch mode power supply regulator, its output voltage, if left unfiltered, will contain a sawtooth ripple voltage at the switching frequency. The output ripple voltage value ranges from 0.5% to 3% of the output voltage. It is caused mainly by the inductor sawtooth ripple current multiplied by the ESR of the output capacitor.

#### Short Voltage Spikes and How to Reduce Them

The regulator output voltage may also contain short voltage spikes at the peaks of the sawtooth waveform (see Figure 25). These voltage spikes are present because of the fast switching action of the output switch, and the parasitic inductance of the output filter capacitor. There are some other important factors such as wiring inductance, stray capacitance, as well as the scope probe used to evaluate these transients, all these contribute to the amplitude of these spikes. To minimize these voltage spikes, low inductance capacitors should be used, and their lead lengths must be kept short. The importance of quality printed circuit board layout design should also be highlighted.

Figure 25. Output Ripple Voltage Waveforms

#### Minimizing the Output Ripple

In order to minimize the output ripple voltage it is possible to enlarge the inductance value of the inductor L1 and/or to use a larger value output capacitor. There is also another way

to smooth the output by means of an additional LC filter (20  $\mu$ H, 100  $\mu$ F), that can be added to the output (see Figure 34) to further reduce the amount of output ripple and transients. With such a filter it is possible to reduce the output ripple voltage transients 10 times or more. Figure 25 shows the difference between filtered and unfiltered output waveforms of the regulator shown in Figure 34.

The lower waveform is from the normal unfiltered output of the converter, while the upper waveform shows the output ripple voltage filtered by an additional LC filter.

### Heatsinking and Thermal Considerations

#### The Through-Hole Package TO-220

The LM2576 is available in two packages, a 5-pin TO-220(T, TV) and a 5-pin surface mount D<sup>2</sup>PAK(D2T). Although the TO-220(T) package needs a heatsink under most conditions, there are some applications that require no heatsink to keep the LM2576 junction temperature within the allowed operating range. Higher ambient temperatures require some heat sinking, either to the printed circuit (PC) board or an external heatsink.

#### The Surface Mount Package D<sup>2</sup>PAK and its Heatsinking

The other type of package, the surface mount D<sup>2</sup>PAK, is designed to be soldered to the copper on the PC board. The copper and the board are the heatsink for this package and the other heat producing components, such as the catch diode and inductor. The PC board copper area that the package is soldered to should be at least 0.4 in<sup>2</sup> (or 260 mm<sup>2</sup>) and ideally should have 2 or more square inches (1300 mm<sup>2</sup>) of 0.0028 inch copper. Additional increases of copper area beyond approximately 6.0 in<sup>2</sup> (4000 mm<sup>2</sup>) will not improve heat dissipation significantly. If further thermal improvements are needed, double sided or multilayer PC boards with large copper areas should be considered. In order to achieve the best thermal performance, it is highly recommended to use wide copper traces as well as large areas of copper in the printed circuit board layout. The only exception to this is the OUTPUT (switch) pin, which should not have large areas of copper (see page 8 'PCB Layout Guideline').

**Thermal Analysis and Design**

The following procedure must be performed to determine whether or not a heatsink will be required. First determine:

1.  $P_D(\text{max})$  maximum regulator power dissipation in the application.
2.  $T_A(\text{max})$  maximum ambient temperature in the application.
3.  $T_J(\text{max})$  maximum allowed junction temperature (125°C for the LM2576). For a conservative design, the maximum junction temperature should not exceed 110°C to assure safe operation. For every additional +10°C temperature rise that the junction must withstand, the estimated operating lifetime of the component is halved.
4.  $R_{\theta JC}$  package thermal resistance junction–case.
5.  $R_{\theta JA}$  package thermal resistance junction–ambient.

(Refer to Absolute Maximum Ratings on page 2 of this data sheet or  $R_{\theta JC}$  and  $R_{\theta JA}$  values).

The following formula is to calculate the approximate total power dissipated by the LM2576:

$$P_D = (V_{in} \times I_Q) + d \times I_{Load} \times V_{sat}$$

where  $d$  is the duty cycle and for buck converter

$$d = \frac{t_{on}}{T} = \frac{V_O}{V_{in}}$$

$I_Q$  (quiescent current) and  $V_{sat}$  can be found in the LM2576 data sheet,

$V_{in}$  is minimum input voltage applied,

$V_O$  is the regulator output voltage,

$I_{Load}$  is the load current.

The dynamic switching losses during turn–on and turn–off can be neglected if proper type catch diode is used.

**Packages Not on a Heatsink (Free–Standing)**

For a free–standing application when no heatsink is used, the junction temperature can be determined by the following expression:

$$T_J = (R_{\theta JA}) (P_D) + T_A$$

where  $(R_{\theta JA})(P_D)$  represents the junction temperature rise caused by the dissipated power and  $T_A$  is the maximum ambient temperature.

**Packages on a Heatsink**

If the actual operating junction temperature is greater than the selected safe operating junction temperature determined in step 3, than a heatsink is required. The junction temperature will be calculated as follows:

$$T_J = P_D (R_{\theta JA} + R_{\theta CS} + R_{\theta SA}) + T_A$$

where  $R_{\theta JC}$  is the thermal resistance junction–case,  $R_{\theta CS}$  is the thermal resistance case–heatsink,  $R_{\theta SA}$  is the thermal resistance heatsink–ambient.

If the actual operating temperature is greater than the selected safe operating junction temperature, then a larger heatsink is required.

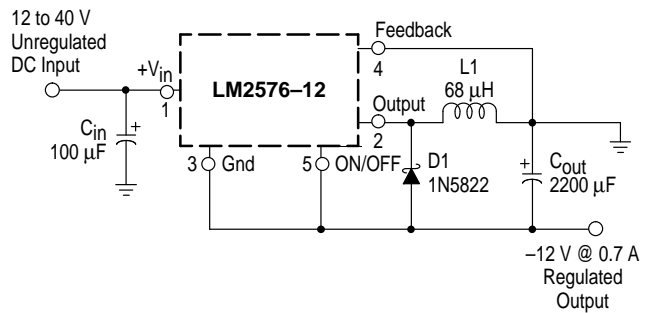

**Some Aspects That can Influence Thermal Design**

It should be noted that the package thermal resistance and the junction temperature rise numbers are all approximate, and there are many factors that will affect these numbers, such as PC board size, shape, thickness, physical position, location, board temperature, as well as whether the surrounding air is moving or still.

Other factors are trace width, total printed circuit copper area, copper thickness, single– or double–sided, multilayer board, the amount of solder on the board or even colour of the traces.

The size, quantity and spacing of other components on the board can also influence its effectiveness to dissipate the heat.

**Figure 26. Inverting Buck–Boost Develops –12 V**

**ADDITIONAL APPLICATIONS**

**Inverting Regulator**

An inverting buck–boost regulator using the LM2576–12 is shown in Figure 26. This circuit converts a positive input voltage to a negative output voltage with a common ground by bootstrapping the regulators ground to the negative output voltage. By grounding the feedback pin, the regulator senses the inverted output voltage and regulates it.

In this example the LM2576–12 is used to generate a –12 V output. The maximum input voltage in this case cannot exceed +28 V because the maximum voltage appearing across the regulator is the absolute sum of the input and output voltages and this must be limited to a maximum of 40 V.

This circuit configuration is able to deliver approximately 0.7 A to the output when the input voltage is 12 V or higher. At lighter loads the minimum input voltage required drops to approximately 4.7 V, because the buck–boost regulator topology can produce an output voltage that, in its absolute value, is either greater or less than the input voltage.

Since the switch currents in this buck–boost configuration are higher than in the standard buck converter topology, the available output current is lower.

This type of buck–boost inverting regulator can also require a larger amount of start–up input current, even for light loads. This may overload an input power source with a current limit less than 5.0 A.

Such an amount of input start–up current is needed for at least 2.0 ms or more. The actual time depends on the output voltage and size of the output capacitor.

Because of the relatively high start–up currents required by this inverting regulator topology, the use of a delayed start–up or an undervoltage lockout circuit is recommended.

Using a delayed start–up arrangement, the input capacitor can charge up to a higher voltage before the switch–mode regulator begins to operate.

The high input current needed for start–up is now partially supplied by the input capacitor  $C_{in}$ .

It has been already mentioned above, that in some situations, the delayed start–up or the undervoltage lockout features could be very useful. A delayed start–up circuit applied to a buck–boost converter is shown in Figure 27, Figure 33 in the “Undervoltage Lockout” section describes an undervoltage lockout feature for the same converter topology.

**Design Recommendations:**

The inverting regulator operates in a different manner than the buck converter and so a different design procedure has to be used to select the inductor  $L_1$  or the output capacitor  $C_{out}$ .

The output capacitor values must be larger than what is normally required for buck converter designs. Low input voltages or high output currents require a large value output capacitor (in the range of thousands of  $\mu F$ ).

The recommended range of inductor values for the inverting converter design is between 68  $\mu H$  and 220  $\mu H$ . To select an inductor with an appropriate current rating, the inductor peak current has to be calculated.

The following formula is used to obtain the peak inductor current:

$$I_{peak} \approx \frac{I_{Load} (V_{in} + |V_{O}|)}{V_{in}} + \frac{V_{in} \times t_{on}}{2L_1}$$

where  $t_{on} = \frac{|V_{O}|}{V_{in} + |V_{O}|} \times \frac{1.0}{f_{osc}}$ , and  $f_{osc} = 52 \text{ kHz}$ .

Under normal continuous inductor current operating conditions, the worst case occurs when  $V_{in}$  is minimal.

**Figure 27. Inverting Buck–Boost Regulator with Delayed start–up**

**Figure 28. Inverting Buck–Boost Regulator Shutdown Circuit Using an Optocoupler**

NOTE: This picture does not show the complete circuit.

With the inverting configuration, the use of the ON/OFF pin requires some level shifting techniques. This is caused by the fact, that the ground pin of the converter IC is no longer at ground. Now, the ON/OFF pin threshold voltage (1.3 V approximately) has to be related to the negative output voltage level. There are many different possible shut down methods, two of them are shown in Figures 28 and 29.

**Figure 29. Inverting Buck–Boost Regulator Shutdown Circuit Using a PNP Transistor**

NOTE: This picture does not show the complete circuit.

**Negative Boost Regulator**

This example is a variation of the buck–boost topology and it is called negative boost regulator. This regulator experiences relatively high switch current, especially at low input voltages. The internal switch current limiting results in lower output load current capability.

The circuit in Figure 30 shows the negative boost configuration. The input voltage in this application ranges from  $-5.0\text{ V}$  to  $-12\text{ V}$  and provides a regulated  $-12\text{ V}$  output. If the input voltage is greater than  $-12\text{ V}$ , the output will rise above  $-12\text{ V}$  accordingly, but will not damage the regulator.

**Figure 30. Negative Boost Regulator**

**Design Recommendations:**

The same design rules as for the previous inverting buck–boost converter can be applied. The output capacitor  $C_{out}$  must be chosen larger than would be required for a what standard buck converter. Low input voltages or high output

currents require a large value output capacitor (in the range of thousands of  $\mu\text{F}$ ). The recommended range of inductor values for the negative boost regulator is the same as for inverting converter design.

Another important point is that these negative boost converters cannot provide current limiting load protection in the event of a short in the output so some other means, such as a fuse, may be necessary to provide the load protection.

**Delayed Start-up**

There are some applications, like the inverting regulator already mentioned above, which require a higher amount of start-up current. In such cases, if the input power source is limited, this delayed start-up feature becomes very useful.

To provide a time delay between the time when the input voltage is applied and the time when the output voltage comes up, the circuit in Figure 31 can be used. As the input voltage is applied, the capacitor  $C_1$  charges up, and the voltage across the resistor  $R_2$  falls down. When the voltage on the ON/OFF pin falls below the threshold value  $1.3\text{ V}$ , the regulator starts up. Resistor  $R_1$  is included to limit the maximum voltage applied to the ON/OFF pin. It reduces the power supply noise sensitivity, and also limits the capacitor  $C_1$  discharge current, but its use is not mandatory.

When a high 50 Hz or 60 Hz (100 Hz or 120 Hz respectively) ripple voltage exists, a long delay time can cause some problems by coupling the ripple into the ON/OFF pin, the regulator could be switched periodically on and off with the line (or double) frequency.

**Figure 31. Delayed start-up Circuitry**

NOTE: This picture does not show the complete circuit.

**Undervoltage Lockout**

Some applications require the regulator to remain off until the input voltage reaches a certain threshold level. Figure 32 shows an undervoltage lockout circuit applied to a buck regulator. A version of this circuit for buck–boost converter is shown in Figure 33. Resistor  $R_3$  pulls the ON/OFF pin high and keeps the regulator off until the input voltage reaches a

## LM2576

predetermined threshold level with respect to the ground Pin 3, which is determined by the following expression:

$$V_{th} \approx V_{Z1} + \left(1.0 + \frac{R2}{R1}\right) V_{BE}(Q1)$$

**Figure 32. Undervoltage Lockout Circuit for Buck Converter**

NOTE: This picture does not show the complete circuit.

The following formula is used to obtain the peak inductor current:

$$I_{peak} \approx \frac{I_{Load} (V_{in} + |V_{O}|)}{V_{in}} + \frac{V_{in} \times t_{on}}{2L_1}$$

where  $t_{on} = \frac{|V_{O}|}{V_{in} + |V_{O}|} \times \frac{1.0}{f_{osc}}$ , and  $f_{osc} = 52 \text{ kHz}$ .

Under normal continuous inductor current operating conditions, the worst case occurs when  $V_{in}$  is minimal.

**Figure 33. Undervoltage Lockout Circuit for Buck-Boost Converter**

NOTE: This picture does not show the complete circuit.

### Adjustable Output, Low-Ripple Power Supply

A 3.0 A output current capability power supply that features an adjustable output voltage is shown in Figure 34.

This regulator delivers 3.0 A into 1.2 V to 35 V output. The input voltage ranges from roughly 3.0 V to 40 V. In order to achieve a 10 or more times reduction of output ripple, an additional L-C filter is included in this circuit.
