

Features

- Adjustable DC Characteristics
- Adjustable Transmit and Receive Gain
- Symmetrical Input of Microphone Amplifier
- Anti-clipping in Transmit Direction
- Automatic Line-loss Compensation
- Built-in Ear Protection
- DTMF and MUTE Input
- Adjustable Side Tone Suppression Independent of Sending and Receiving Amplification
- Integrated Amplifier for Loud-hearing Operation
- Anti-clipping for Loudspeaker Amplifier
- Improved Acoustical Feedback Suppression
- Selectable Line Impedance
- Voice Switch
- Supply Voltages for All Functional Blocks of a Subscriber Set
- Operation Possible from 10-mA Line Current

Benefits

- Complete System Integration of Analog Signal Processing on One Chip
- Very Few External Components

Applications

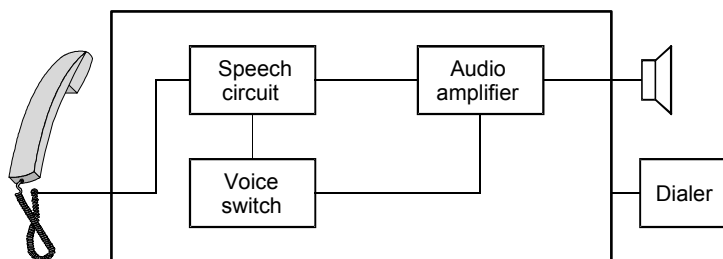

- Feature Phones
- Answering Machines
- Fax Machines
- Speaker Phones

Description

The telephone circuit U4089B-M is a linear integrated circuit for use in feature phones, answering machines and fax machines. It contains the speech circuit, side tone equivalent and ear protection rectifiers. The circuit is line-powered and contains all components necessary for the amplification of signals and adaptation to the line.

An integrated voice switch with a loudspeaker amplifier enables loud-hearing or hands-free operation. With an anti-feedback function, acoustical feedback during loud-hearing can be reduced significantly. The generated supply voltage is suitable for a wide range of peripheral circuits.

Figure 2. Block Diagram

Pin Configuration

Figure 3. Pinning SSO44

Pin Description

Pin	Symbol	Function
1	DTMF	Input for DTMF signals. Also used for the answering machine and hands-free input.
3	MIC 2	Non-inverting input of microphone amplifier
4	MIC 1	Inverting input of microphone amplifier
6	IND	The internal equivalent inductance of the circuit is proportional to the value of the capacitor at this pin. A resistor connected to ground may be used to reduce the DC line voltage.
7	V_L	Line voltage
8	GND	Reference point for DC- and AC-output signals
9	SENSE	A small resistor (fixed) connected from this pin to V_L sets the slope of the DC characteristic and also affects the line-length equalization characteristics and the line current at which the loudspeaker amplifier is switched on.
10	V_B	Unregulated supply voltage for peripheral circuits (voice switch); limited to typically 7 V
11	SAO	Output of loudspeaker amplifier
13	V_{MP}	Regulated 3.3 V supply voltage for peripheral circuits. The maximum output current is 2 mA.
20	IMPSEL	Control input for selection of line impedance 1) 600 Ω 2) 900 Ω 3) Mute of second transmit stage (TXA); also used for indication of external supply (answering machine); last chosen impedance is stored
21	TSACL	Time constant of anti-clipping of speaker amplifier
22	GSA	Current input for setting the gain of the speaker amplifier. Adjustment characteristic is logarithmical. For $RGSA > 2 \text{ M}\Omega$, the speaker amplifier is switched off.
23	SA I	Speaker amplifier input (for loudspeaker, tone ringer and hands-free use)
24	MUTX	Three-state input of transmit mute: 1) Speech condition; inputs MIC1/MIC2 active 2) DTMF condition; input DTMF active. A part of the input signal is passed to the receiving amplifier as a confidence signal during dialing. 3) Input DTMF used for answering machine and hands-free use; receive branch is not affected.
25	ATAFS	Attenuation of acoustical feedback suppression. Maximum attenuation of the AFS circuit is set by a resistor at this pin. Without the resistor, AFS is switched off.
26	INLDT	Input of transmit level detector
27	INLDR	Input of receive level detector
28	TLDT	Time constant of transmit level detector
29	TLDR	Time constant of receive level detector
30	AGA	Automatic gain adjustment with line current. A resistor connected from this pin to GND sets the starting point. Max. gain change is 6 dB.
31	IREF	Internal reference current generation; $RREF = 62 \text{ k}\Omega$; $IREF = 20 \mu\text{A}$
32	STO	Side tone reduction output. Output resistance is approximately 300 Ω . Maximum load impedance is 10 k Ω .
33	V_M	Reference node for microphone, earphone and loudspeaker amplifier. Supply for electret microphone ($IM \leq 300 \mu\text{A}$).
36	STI	Input for side-tone network
39	RECO	Output of receiving amplifier
40	G_R	A resistor connected from this pin to GND sets the receiving amplification of the circuit; amplifier RA1 can be muted by applying V_{MP} to G_R
41	TTXA	Time constant of anti-clipping in transmit path
42	RECIN	Input of receiving path; input impedance is typically 80 k Ω
44	G_T	A resistor from this pin to GND sets the amplification of the microphone and DTMF signals; the input amplifier can be muted by applying V_{MP} to G_T .

DC Line Interface and Supply-voltage Generation

The DC line interface consists of an electronic inductance and an output stage which charges the capacitor at V_B . The value of the equivalent inductance is given by:

$$L = R_{\text{SENSE}} \times C_{\text{IND}} \times (R_{\text{DC}} \times R_{30}) / (R_{\text{DC}} + R_{30})$$

In order to improve the supply during worst-case operating conditions, the PNP current source (I_{BOPT}) supplies an extra amount of current to the supply voltages when the NPN in parallel is unable to conduct current.

The U4089B-M contains a series regulator which provides a supply voltage V_{MP} of 3.3 V at the 2 mA suitable for a microprocessor.

Figure 4. DC Line Interface with Electronic Inductance and Generation of Regulated and Unregulated Supply

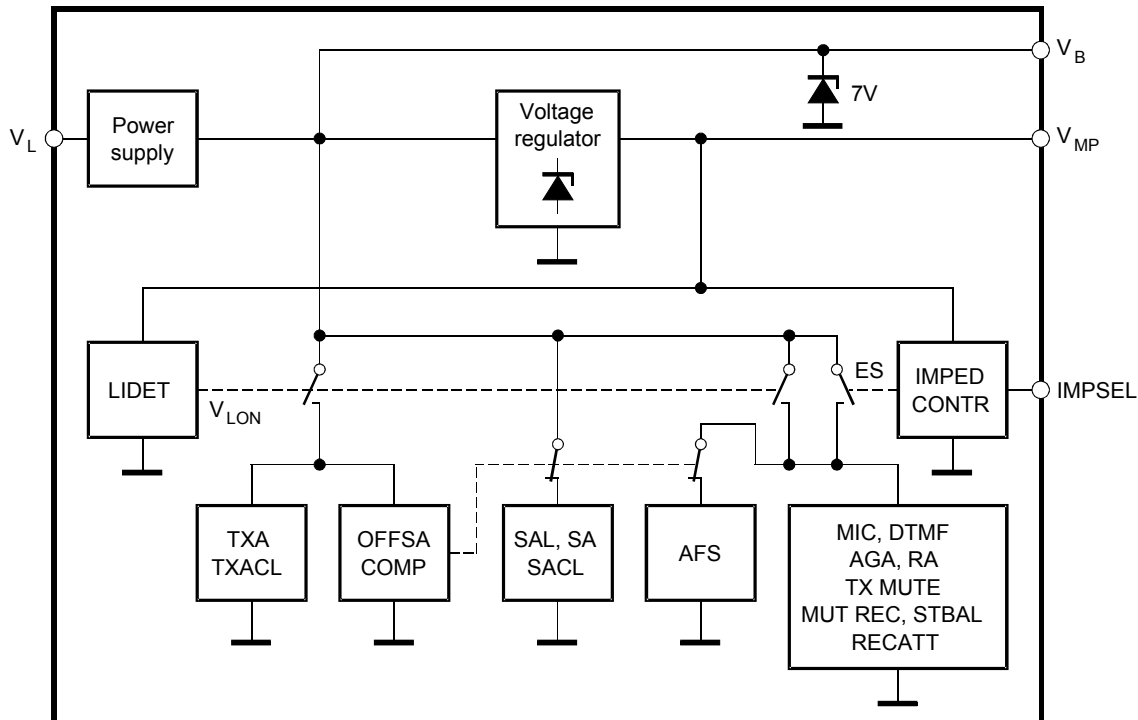

Figure 5. Functional Blocks for Power Supply

1. In speech condition, the system is supplied by the line current. If the LIDET-block detects a line voltage above the fixed threshold (1.9 V), the internal signal VLON is activated, thus switching on all blocks of the chip.
For line voltages below 1.9 V, the switches remain in their quiescent state as shown in Figure 5.
OFFSACOMP disables the group listening feature (SAI, SA, SACL, AFS) below line currents of approximately 10 mA.
2. Selecting IMPSEL = high impedance activates all switches at the ES line.

Acoustic Feedback Suppression

Acoustical feedback from the loudspeaker to the handset microphone may cause instability in the system. The U4089B-M offers a very efficient feedback suppression circuit which uses a modified voice switch topology. Figure 6 shows the basic system configuration.

Two attenuators (TX ATT and RX ATT) reduce the critical loop gain by introducing an externally adjustable amount of loss either in the transmit or in the receive path. The sliding control in block ATT CONTR determines whether the TX or the RX signal has to be attenuated. The overall loop gain remains constant under all operating conditions.

Selection of the active channel is made by comparison of the logarithmically compressed TX and RX envelope curves.

The system configuration for group listening, which is realized in the U4089B-M, is illustrated in Figure 7. TXA and SAI represent the two attenuators; the logarithmic envelope detectors are shown in a simplified way (operational amplifiers with two diodes).

Figure 6. Basic Voice-switch System

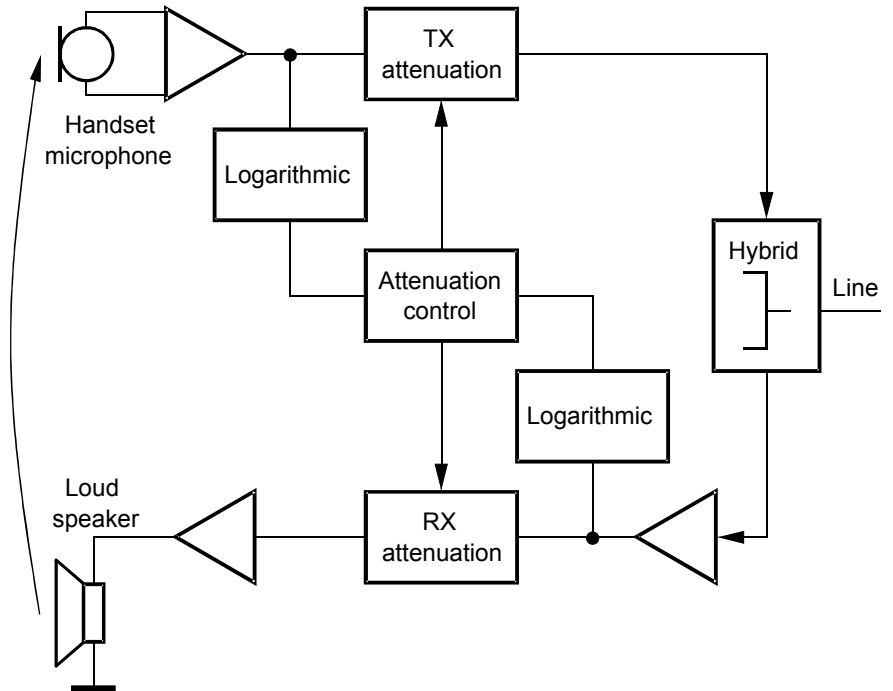

Figure 7. Integration of the Acoustic Feedback-suppression Circuit Into the Speech Circuit Environment

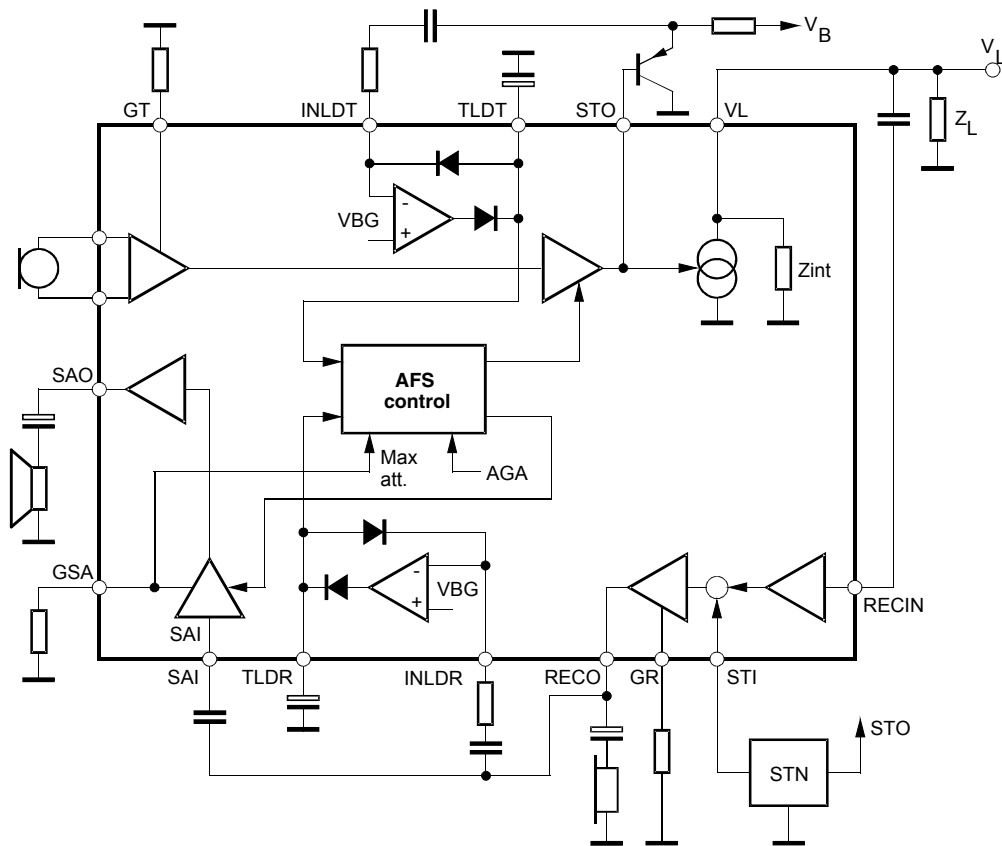

Figure 8. Acoustic Feedback Suppression by Alternative Control of Transmit and Speaker Amplifier Gain

A detailed diagram of the AFS (Acoustic Feedback Suppression) is given in Figure 8. Receive and transmit signals are first processed by logarithmic rectifiers in order to produce the speech envelopes at TLDT and RLDT. After amplification, a decision is made by the differential pair of which direction should be transmitted.

The attenuation of the controlled amplifiers TXA and SAI is determined by the emitter current I_{AT} which is comprised of three parts:

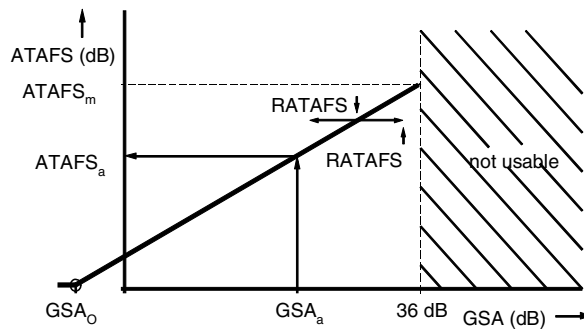

- I_{ATAFS} Sets maximum attenuation
- I_{ATGSA} Decreases the attenuation when speaker amplifier gain is reduced
- I_{AGAFS} Decreases the attenuation according to the loop-gain reduction caused by the AGA function

$$I_{AT} = I_{ATAFS} - I_{ATGSA} - I_{AGAFS}$$

$$\Delta G = I_{AT} \times 0.67 \text{ dB}/\mu\text{A}$$

Figure 9 illustrates the principal relationship between the speaker amplifier gain (GSA) and attenuation of AFS (ATAFS). Both parameters can be adjusted independently, but the internal coupling between them has to be considered. The maximum GSA value to be used is 36 dB. The shape of the characteristic is moved in the x-direction by adjusting resistor RATAFS, thus changing $ATAFS_m$. The actual value of the attenuation ($ATAFS_a$), however, can be determined by reading the value which belongs to the actual gain GSA_a . If the speaker amplifier gain is reduced, the attenuation of AFS is automatically reduced by the same amount in order to achieve a constant loop gain. Zero attenuation is set for speaker gains $GSA \geq GSA_0 = 36 \text{ dB} - ATAFS_m$.

Figure 9. Reducing Speaker Amplifier Gain Results in an Equal Reduction of AFS Attenuation

Operating Range of Speaker Amplifier

The basic behavior is illustrated in Figure 10. Actual values of ILOFF/ILOFF vary slightly with the adjustment of the DC characteristics and the selection of the internal line impedance.
