

# US1261

## DUAL 6A AND 1A LOW DROPOUT POSITIVE FIXED OUTPUT REGULATOR

### FEATURES

- Guaranteed to provide 1.5V and 2.5V Supplies with 3.1V input.
- Fast Transient Response
- 1% Voltage Reference Initial Accuracy
- Built in Thermal Shutdown

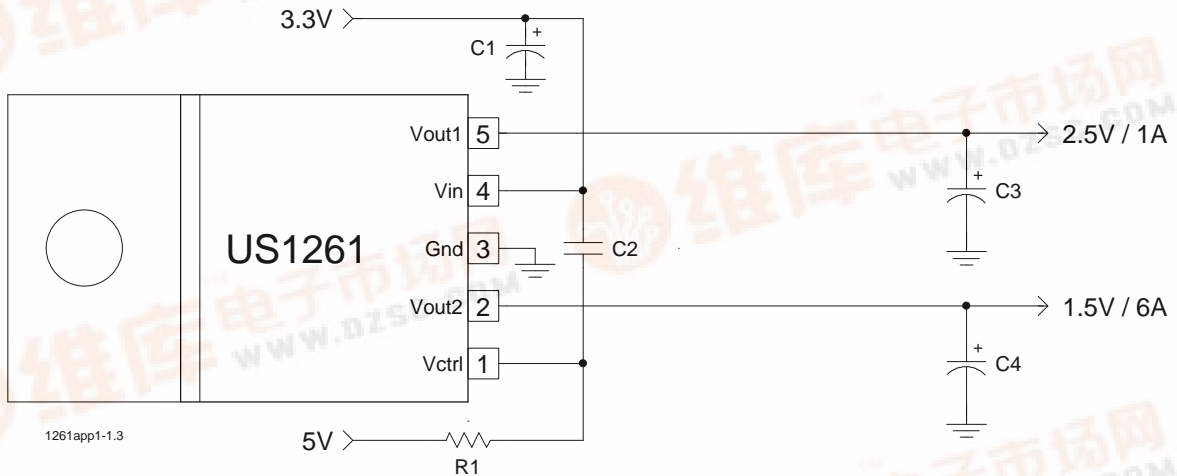

### APPLICATIONS

- Pentium II Processor Applications

### DESCRIPTION

The US1261 product using a **proprietary process** combines a dual low dropout regulators with fixed outputs of 1.5V and 2.5V in a **single package** with the 1.5V output having a minimum of **6A** and the 2.5V having a **1A** output current capability. This product is specifically designed to provide well regulated supplies from **3.3V to generate 1.5V for GTL+ termination resistor supply and 2.5V clock supply for the new generation of the Pentium II processor applications.**

### TYPICAL APPLICATION

Typical application of US1261 in a Pentium II processor application

**Note 1** : Low duty cycle pulse testing with Kelvin connections are required in order to maintain accurate data.  
**Note 2** : Drop-out voltage is defined as the minimum differential voltage between  $V_{in}$  and  $V_{out}$  required to maintain regulation at  $V_{out}$ . It is measured when the output voltage drops 1% below its nominal value.

**Note 3** : Minimum load current is defined as the minimum current required at the output in order for the output voltage to maintain regulation. Typically the resistor dividers are selected such that it automatically maintains this current.

## PIN DESCRIPTIONS

| PIN # | PIN SYMBOL | PIN DESCRIPTION   |
|-------|------------|---|
| 2     | Vout2      | The output #2 (high current) of the regulator. A minimum of 100uF capacitor must be connected from this pin to ground to insure stability.  |
| 5     | Vout1      | The output #1 (low current) of the regulator. A minimum of 100uF capacitor must be connected from this pin to ground to insure stability.   |
| 4     | Vin        | The power input pin of the regulator. Typically a large storage capacitor is connected from this pin to ground to insure that the input voltage does not sag below the minimum drop out voltage during the load transient response. This pin must always be higher than both Vout pins by the amount of the dropout voltage(see datasheet) in order for the device to regulate properly.                            |
| 3     | Gnd        | This pin is connected to GND. It is also the TAB of the package.  |
| 1     | Vctrl      | The control input pin of the regulator. This pin via a 10Ω resistor is connected to the 5V supply to provide the base current for the pass transistor of both regulators. This allows the regulator to have very low dropout voltage which allows one to generate a well regulated 2.5V supply from the 3.3V input. A high frequency, 1 uF capacitor is connected between this pin and Vin pin to insure stability. |

# US1261

## APPLICATION INFORMATION

### Introduction

The US1261 is a dual fixed output Low Dropout (LDO) regulator available in a 5 pin TO-220 or TO-263 packages. This voltage regulator is designed specifically for PentiumII processor applications requiring 2.5V and 1.5 V supplies, **eliminating the need for a second regulator resulting in lower overall system cost.** The US1261 is designed to take advantage of 5V supply to provide the drive for the pass transistor, allowing 2.5V supply to be generated from 3.3V input. This feature improves the power dissipation of the 2.5V regulator substantially allowing a smaller heat sink to be used for the application. Compared to the US1260 dual adjustable regulator, the US1261 includes the resistor dividers that are otherwise needed with the US1260, eliminating 4 external components and their tolerances, resulting in a more accurate initial accuracy for each output voltage. Other features of the device include; fast response to sudden load current changes, such as GTL+ termination application and thermal shutdown protection to protect the device if an overload condition occurs.

### Stability

The US1261 requires the use of an output capacitor as part of the frequency compensation in order to make the regulator stable. Typical designs for the microprocessor applications use standard electrolytic capacitors with typical ESR in the range of 50 to 100 mΩ and the output capacitance of 500 to 1000uF. Fortunately as the capacitance increases, the ESR decreases resulting in a fixed RC time constant. The US1261 takes advantage of this phenomena in making the overall regulator loop stable. For most applications a minimum of 100uF aluminum electrolytic capacitor with the maximum ESR of 0.3Ω such as Sanyo, MVGX series, Panasonic FA series as well as the Nichicon PL series insures both stability and good transient response. The US1261 also requires a 1 uF ceramic capacitor connected from Vin to Vctrl and a 10Ω, 0.1W resistor in series with Vctrl pin in order to further insure stability.

### Thermal Design

The US1261 incorporates an internal thermal shutdown that protects the device when the junction temperature exceeds the maximum allowable junction temperature. Although this device can operate with junction temperatures in the range of 150°C, it is recommended that the

selected heat sink be chosen such that during maximum continuous load operation the junction temperature is kept below this number. Two examples are given which shows the steps in selecting the proper regulator heat sink for driving the Pentium II processor GTL+ termination resistors and the Clock IC using 1261 in TO220 and TO-263 packages.

#### Example # 1

Assuming the following specifications :

$$V_{IN} = 3.3V$$

$$V_{OUT2} = 1.5V$$

$$V_{OUT1} = 2.5V$$

$$I_{OUT2\ MAX} = 5.4A$$

$$I_{OUT1\ MAX} = 0.4A$$

$$T_A = 35^\circ C$$

The steps for selecting a proper heat sink to keep the junction temperature below 135°C is given as :

1) Calculate the maximum power dissipation using :

$$P_D = I_{OUT1} \times (V_{IN} - V_{OUT1}) + I_{OUT2} \times (V_{IN} - V_{OUT2})$$

$$P_D = 0.4 \times (3.3 - 2.5) + 5.4 \times (3.3 - 1.5) = 10W$$

2) Select a package from the datasheet and record its junction to case (or Tab) thermal resistance.

Selecting TO220 package gives us :

$$\theta_{JC} = 2.7^\circ C/W$$

3) Assuming that the heat sink is Black Anodized, calculate the maximum Heat sink temperature allowed : Assume ,  $\theta_{CS} = 0.05^\circ C/W$  (Heat sink to Case thermal resistance for Black Anodized)

$$T_S = T_J - P_D \times (\theta_{JC} + \theta_{CS})$$

$$T_S = 135 - 10 \times (2.7 + 0.05) = 107.4^\circ C$$

4) With the maximum heat sink temperature calculated in the previous step, the Heat Sink to Air thermal resistance  $\theta_{SA}$  is calculated as follows :

$$\Delta T = T_S - T_A = 107.4 - 35 = 72.4^\circ C$$

$$\theta_{SA} = \frac{\Delta T}{P_D}$$

$$\theta_{SA} = \frac{72.4}{10} = 7.24^\circ C/W$$

5) Next , a heat sink with lower  $\theta_{SA}$  than the one calculated in step 4 must be selected. One way to do this is to simply look at the graphs of the "Heat Sink Temp Rise Above the Ambient" vs. the "Power Dissipation" and

select a heat sink that results in lower temperature rise than the one calculated in previous step. The following heat sinks from AAVID and Thermalloy meet this criteria.

|            | Air Flow (LFM) |         |         |         |         |
|------------|----------------|---------|---------|---------|---------|
|            | 0              | 100     | 200     | 300     | 400     |
| Thermalloy | 7021B          | 7020B   | 6021PB  | 7173D   | 7141D   |
| AAVID      | 593101B        | 551002B | 534202B | 577102B | 576802B |

## Layout Consideration

The US1261 like all other high speed linear regulators need to be properly laid out to insure stable operation. The most important component is the **output capacitor, which needs to be placed close to the output pin and connected to this pin using a plane connection with a low inductance path.**

Note : For further information regarding the above companies and their latest product offering and application support contact your local representative or the numbers listed below:

Thermalloy      PH# (214) 243-4321  
AAVID            PH# (603) 528-3400

### Example # 2 :

Assuming the following specifications :

$$V_{IN} = 3.3V$$

$$V_{OUT2} = 1.5 V$$

$$V_{OUT1} = 2.5 V$$

$$I_{OUT2 MAX} = 1.5A$$

$$I_{OUT1 MAX} = 0.2 A$$

$$T_A = 35^{\circ}C$$

The steps for selecting a proper heat sink to keep the junction temperature below 135°C is given as :

1) Calculate the maximum power dissipation using :

$$P_D = I_{OUT1} \times (V_{IN} - V_{OUT1}) + I_{OUT2} \times (V_{IN} - V_{OUT2})$$

$$P_D = 0.2 \times (3.3 - 2.5) + 1.5 \times (3.3 - 1.5) = 2.86 W$$

2) Assuming a TO-263 surface mount package, the junction to ambient thermal resistance of the package is:

$$\theta_{JA} = 30^{\circ}C / W \text{ for } 1" \text{ square pad area}$$

3) The maximum junction temperature of the device is calculated using the equation below :

$$T_J = T_A + P_D \times \theta_{JA}$$

$$T_J = 35 + 2.86 \times 30 = 121^{\circ}C$$

Since this is lower than our selected 135°C maximum junction temperature (150°C is the thermal shutdown of the device), TO-263 package is a suitable package for our application.
