VITELIC

V53C104B
HIGH PERFORMANCE, LOW POWER
256K X 4 BIT FAST PAGE MODE
CMOS DYNAMIC RAM

PRELIMINARY

HIGH PERFORMANCE V53C104B	60/60L	70/70L	80/80L
Max. $\overline{RAS}$ Access Time, (t_{RAC})	60 ns	70 ns	80 ns
Max. Column Address Access Time, (t_{CAA})	30 ns	35 ns	40 ns
Min. Fast Page Mode Cycle Time, (t_{PC})	40 ns	45 ns	50 ns
Min. Read/Write Cycle Time, (t_{RC})	120 ns	130 ns	150 ns

LOW POWER V53C104BL	60L	70L	80L
Max. CMOS Standby Current, (I_{DD6})	200µA	200µA	200µA

Features

- 256K x 4 Organization
- RAS access time: 60,70,80 ns
- Low power dissipation for V53C104B-80
  - Operating Current – 70 mA max.
  - TTL Standby Current – 2.0 mA max.
- Low CMOS Stanby Curent
  - V53C104B – 1.0 mA max.
  - V53C104BL – 0.2 mA max.
- Read-Modify-Write, RAS-Only Refresh, $\overline{CAS}$-Before-$\overline{RAS}$ Refresh capability.
- Common I/O capability
- Refresh Interval
  - V53C104B – 512 cycles/8ms
  - V53C104BL – 512 cycles/64ms
- On-chip substrate bias generator
- Fast Page Mode for a sustained data rate greater than 25 MHz
- Standard packages are 20 pin Plastic DIP and 26/20 pin SOJ
- Low Battery Back-up Current
  - V53C104BL – 300 µA max.
  - 200 µA max. available on request

Description

The Vitelic V53C104B is a high speed 262,144 x 4 bit CMOS dynamic random access memory. Fabricated with Vitelic's VICMOS IV technology, the V53C104B offers a combination of features: Fast Page Mode for high data bandwidth, fast usable speed, CMOS standby current and, on request, extended refresh for very low data retention power (V53C104BL).

All inputs and outputs are TTL compatible. Input and output capacitances are significantly lowered to allow increased system performance. Fast Page Mode operation allows random access of up to 512 (x4) bits within a row with cycle times as short as 40 ns. Because of static circuitry, the $\overline{CAS}$ clock is not in the critical timing path. The flow-through column address latches allow address pipelining while relaxing many critical system timing requirements for fast usable speed. These features make the V53C104B ideally suited for graphics, digital signal processing and high performance computing systems.

The V53C104BL offers a maximum data retention power of 1.65 mW when operating in CMOS standby mode and performing $\overline{CAS}$-before-$\overline{RAS}$ refresh cycles.

1. I_{DD} is dependent on output loading when the device output is selected. Specified I_{DD} (max.) is measured with the output open.
2. I_{DD} is dependent upon the number of address transitions. Specified I_{DD} (max.) is measured with a maximum of two transitions per address cycle in Fast Page Mode.
3. Specified V_{IL} (min.) is steady state operating. During transitions, V_{IL} (min.) may undershoot to −1.0 V for a period not to exceed 20 ns. All AC parameters are measured with V_{IL} (min.) ≥ V_{SS} and V_{IH} (max.) ≤ V_{DD}.
4. t_{RCD} (max.) is specified for reference only. Operation within t_{RCD} (max.) limits insures that t_{RAC} (max.) and t_{CAA} (max.) can be met. If t_{RCD} is greater than the specified t_{RCD} (max.), the access time is controlled by t_{CAA} and t_{CAC}.
5. Either t_{RRH} or t_{RCH} must be satisified for a Read Cycle to occur.
6. Measured with a load equivalent to two TTL inputs and 100 pF.
7. Access time is determined by the longest of t_{CAA}, t_{CAC} and t_{CAP}.
8. Assumes that $t_{RAD} \leq t_{RAD}$ (max.). If t_{RAD} is greater than t_{RAD} (max.), t_{RAC} will increase by the amount that t_{RAD} exceeds t_{RAD} (max.).
9. Assumes that $t_{RCD} \leq t_{RCD}$ (max.). If t_{RCD} is greater than t_{RCD} (max.), t_{RAC} will increase by the amount that t_{RCD} exceeds t_{RCD} (max.).
10. Assumes that $t_{RAD} \geq t_{RAD}$ (max.).
11. Operation within the t_{RAD} (max.) limit ensures that t_{RAC} (max.) can be met. t_{RAD} (max.) is specified as a reference point only. If t_{RAD} is greater than the specified t_{RAD} (max.) limit, the access time is controlled by t_{CAA} and t_{CAC}.
12. t_{WCS}, t_{RWD}, t_{AWD} and t_{CWD} are not restrictive operating parameters.
13. t_{WCS} (min.) must be satisfied in an Early Write Cycle.
14. t_{DS} and t_{DH} are referenced to the latter occurrence of $\overline{CAS}$ or $\overline{WE}$.
15. t_T is measured between V_{IH} (min.) and V_{IL} (max.). AC-measurements assume t_T = 5 ns.
16. Assumes a three-state test load (5 pF and a 380 Ohm Thevenin equivalent).
17. An initial 200 µs pause and 8 $\overline{RAS}$-containing cycles are required when exiting an extended period of bias without clocks. An extended period of time without clocks is defined as one that exceeds the specified Refresh Interval.
18. This is battery backup data retention mode under $\overline{CAS}$ before $\overline{RAS}$ refresh cycles.

    t_{RC} = 125 µs (125 µs x 512 = 64 ms)

    $t_{RAS} = t_{RAS}$ (min) to 1 µs

    Input voltages : $\overline{RAS}$ and $\overline{CAS}$ $V_{IH} > V_{DD} - 0.2$ V

    $V_{IL} < 0.2$ V

    $\overline{WE}$ and $\overline{OE}$ $V_{IN} > V_{DD} - 0.2$ V

    All other inputs at stable V_{IH} or V_{IL}

Functional Description

The V53C104B is a CMOS dynamic RAM optimized for high data bandwidth, low power applications. It is functionally similar to a traditional dynamic RAM. The V53C104B reads and writes data by multiplexing an 18-bit address into a 9-bit row and a 9-bit column address. The row address is latched by the Row Address Strobe ($\overline{RAS}$). The column address "flows through" an internal address buffer and is latched by the Column Address Strobe ($\overline{CAS}$). Because access time is primarily dependent on a valid column address rather than the precise time that the $\overline{CAS}$ edge occurs, the delay time from $\overline{RAS}$ to $\overline{CAS}$ has little effect on the access time.

Memory Cycle

A memory cycle is initiated by bringing $\overline{RAS}$ low. Any memory cycle, once initiated, must not be ended or aborted before the minimum t_{RAS} time has expired. This ensures proper device operation and data integrity. A new cycle must not be initiated until the minimum precharge time t_{RP}/t_{CP} has elapsed.

Read Cycle

A Read cycle is performed by holding the Write Enable ($\overline{WE}$) signal High during a $\overline{RAS}/\overline{CAS}$ operation. The column address must be held for a minimum specified by t_{AR}. Data Out becomes valid only when t_{OAC}, t_{RAC}, t_{CAA} and t_{CAC} are all satisifed. As a result, the access time is dependent on the timing relationships between these parameters. For example, the access time is limited by t_{CAA} when t_{RAC}, t_{CAC} and t_{OAC} are all satisfied.

Write Cycle

A Write Cycle is performed by taking $\overline{WE}$ and $\overline{CAS}$ low during a $\overline{RAS}$ operation. The column address is latched by $\overline{CAS}$. The Write Cycle can be $\overline{WE}$ controlled or $\overline{CAS}$ controlled depending on whether $\overline{WE}$ or $\overline{CAS}$ falls later. Consequently, the input data must be valid at or before the falling edge of $\overline{WE}$ or $\overline{CAS}$, whichever occurs last. In the $\overline{CAS}$-controlled Write Cycle, when the leading edge of $\overline{WE}$ occurs prior to the $\overline{CAS}$ low transition, the I/O data pins will be in the High-Z state at the beginning of the Write function. Ending the Write with $\overline{RAS}$ or $\overline{CAS}$ will maintain the output in the High-Z state.

In the $\overline{WE}$ controlled Write Cycle, $\overline{OE}$ must be in the high state and t_{OED} must be satisfied.

Refresh Cycle

To retain data, 512 Refresh Cycles are required in each 8 ms period. There are two ways to refresh the memory:

1. By clocking each of the 512 row addresses (A_0 through A_8) with $\overline{RAS}$ at least once every 8 ms. Any Read, Write, Read-Modify-Write or $\overline{RAS}$-only cycle refreshes the addressed row.
2. Using a $\overline{CAS}$-before-$\overline{RAS}$ Refresh Cycle. If $\overline{CAS}$ makes a transition from low to high to low after the previous cycle and before $\overline{RAS}$ falls, $\overline{CAS}$-before-$\overline{RAS}$ refresh is activated. The V53C104B uses the output of an internal 9-bit counter as the source of row addresses and ignore external address inputs.

$\overline{CAS}$-before-$\overline{RAS}$ is a "refresh-only" mode and no data access or device selection is allowed. Thus, the output remains in the High-Z state during the cycle. A $\overline{CAS}$-before-$\overline{RAS}$ counter test mode is provided to ensure reliable operation of the internal refresh counter.

Data Retention Mode

The V53C104B offers a CMOS standby mode that is entered by causing the $\overline{RAS}$ clock to swing between a valid V_{IL} and an "extra high" V_{IH} within 0.2 V of V_{DD}. While the $\overline{RAS}$ clock is at the "extra high" level, the V53C104B power consumption is reduced to the low I_{DD6} level. Overall I_{DD} consumption when operating in this mode can be calculated as follows:

$$I = \frac{(t_{RC}) \times (I_{DD1}) + (t_{RX}-t_{RC}) \times (I_{DD6})}{t_{RX}}$$

Where: t_{RC} = Refresh Cycle Time
t_{RX} = Refresh Interval / 512

Fast Page Mode Operation

Fast Page Mode operation permits all 512 columns within a selected row of the device to be randomly accessed at a high data rate. Maintaining $\overline{RAS}$ low while performing successive $\overline{CAS}$ cycles retains the row address internally and eliminates the need to reapply it for each cycle. The column address buffer acts as a transparent or flow-through latch while $\overline{CAS}$ is high. Thus, access begins from the occurrence of a valid column address rather than from the falling edge of $\overline{CAS}$, eliminating t_{ASC} and t_T from the critical timing path. $\overline{CAS}$ latches the address into the column address buffer and acts as an output enable. During Fast Page Mode operation, Read, Write, Read-Modify-Write or Read-Write-Read cycles are possible at random addresses within a row. Following the initial entry cycle into Fast Page Mode, access is t_{CAA} or t_{CAP} controlled. If the column address is valid prior to the rising edge of $\overline{CAS}$, the access time is referenced to the $\overline{CAS}$ rising edge and is specified by t_{CAP}. If the column address is valid after the rising $\overline{CAS}$ edge, access is timed from the occurrence of a valid address and is specified by t_{CAA}. In both cases, the falling edge of $\overline{CAS}$ latches the address and enables the output.

Fast Page Mode provides a sustained data rate of 25 MHz for applications that require high data rates such as bit-mapped graphics or high-speed signal processing. The following equation can be used to calculate the maximum data rate:

$$\text{Data Rate} = \frac{512}{t_{RC} + 511 \times t_{PC}}$$

Data Output Operation

The V53C104B Input/Output is controlled by $\overline{OE}$, $\overline{CAS}$, $\overline{WE}$ and $\overline{RAS}$. A $\overline{RAS}$ low transition enables the transfer of data to and from the selected row address in the Memory Array. A $\overline{RAS}$ high transition disables data transfer and latches the output data if the output is enabled. After a memory cycle is initiated with a $\overline{RAS}$ low transition, a $\overline{CAS}$ low transition or $\overline{CAS}$ low level enables the internal I/O path. A $\overline{CAS}$ high transition or a $\overline{CAS}$ high level disables the I/O path and the output driver if it is enabled. A $\overline{CAS}$ low transition while $\overline{RAS}$ is high has no effect on the I/O data path or on the output drivers. The output drivers, when otherwise enabled, can be disabled by holding $\overline{OE}$ high. The $\overline{OE}$ signal has no effect on any data stored in the output latches. A $\overline{WE}$ low level can also disable the output drivers when $\overline{CAS}$ is low. During a Write cycle, if $\overline{WE}$ goes low at a time in relationship to $\overline{CAS}$ that would normally cause the outputs to be active, it is necessary to use $\overline{OE}$ to disable the output drivers prior to the $\overline{WE}$ low transition to allow Data In Setup Time (t_{DS}) to be satisfied.

Power-On

After application of the V_{DD} supply, an initial pause of 200 µs is required followed by a minimum of 8 initialization cycles (any combination of cycles containing a $\overline{RAS}$ clock). Eight initialization cycles are required after extended periods of bias without clocks (greater than the Refresh Interval).

During Power-On, the V_{DD} current requirement of the V53C104B is dependent on the input levels of $\overline{RAS}$ and $\overline{CAS}$. If $\overline{RAS}$ is low during Power-On, the device will go into an active cycle and I_{DD} will exhibit current transients. It is recommended that $\overline{RAS}$ and $\overline{CAS}$ track with V_{DD} or be held at a valid V_{IH} during Power-On to avoid current surges.

Table 1. Vitelic V53C104B Data Output *Operation for Various Cycle Types*

Cycle Type	I/O State
Read Cycles	Data from Addressed Memory Cell
$\overline{CAS}$-Controlled Write Cycle (Early Write)	High-Z
$\overline{WE}$-Controlled Write Cycle (Late Write)	$\overline{OE}$ Controlled. High $\overline{OE}$ = High-Z I/Os
Read-Modify-Write Cycles	Data from Addressed Memory Cell
Fast Page Mode Read	Data from Addressed Memory Cell
Fast Page Mode Write Cycle (Early Write)	High-Z
Fast Page Mode Read-Modify-Write Cycle	Data from Addressed Memory Cell
$\overline{RAS}$-only Refresh	High-Z
$\overline{CAS}$-before-$\overline{RAS}$ Refresh Cycle	Data remains as in previous cycle
$\overline{CAS}$-only Cycles	High-Z
