### Typical Application Circuits

The load conditions at Q depend on the permissible power dissipation of the power transistors used. The pulsed power dissipation in case of a short circuit must be observed.

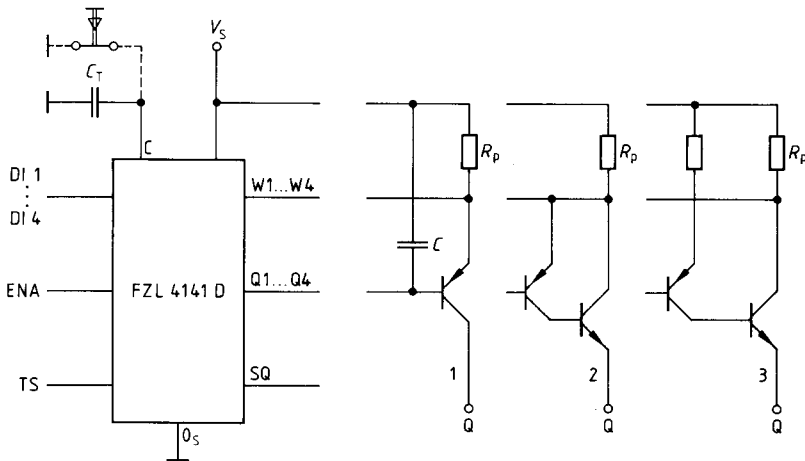

In order to suppress oscillations of the power stage in case of a short circuit, a capacitor C at Q1 to Q4 is necessary if e.g., fast switching transistors are used.

Typical value C approx. 20 nF.

The output circuit 1 is suited for currents up to approx.  $I_Q = 100$  mA.

The output circuits 2 and 3 are suited for currents up to approx.  $I_Q = 2$  A. A minimum power dissipation can be achieved with circuit 3.

A break key in parallel to  $C_T$  allows a manual switch-on in case of short circuit.

$R_p$  = Precision resistor (current measurement)

$C_T = 0.8 \times t_p$  ( nF,  $\mu$ s)

$t_p$  = Short-circuit current pulse length

### Note

Circuit 1 does not permit a capacitor between Q1 and Q4 and the collector.

Circuit 2 does not permit a capacitor between Q1 and Q4 and base or emitter, respectively.

Otherwise too high current spikes would arise in case of a short circuit.

## Typical Application of Short-Circuit Signaling Output SQ

### 1. LED Display

### 2. TTL/CMOS/LSL Driving

If the pulses that appear at SQ during clocked operation disturb the remainder of the circuit, a lowpass filter will be necessary. For a load current of  $I_{SQ} = 1 \text{ mA}$  a capacitor C of approx. 10 nF is necessary to limit the output pulses of up to 10  $\mu\text{s}$  (depending on  $C_T$ ) to 1 V. Signaling occurs after approx. 50  $\mu\text{s}$ .
