

High-Speed Low Power CAN Transceiver

Description

The AMIS-42665 CAN transceiver is the interface between a controller area network (CAN) protocol controller and the physical bus and may be used in both 12 V and 24 V systems. The transceiver provides differential transmit capability to the bus and differential receive capability to the CAN controller.

Due to the wide common-mode voltage range of the receiver inputs, the AMIS-42665 is able to reach outstanding levels of electromagnetic susceptibility (EMS). Similarly, extremely low electromagnetic emission (EME) is achieved by the excellent matching of the output signals.

The AMIS-42665 is a new addition to the CAN high-speed transceiver family and offers the following additional features:

Features

- Wake-up (WU) Over Bus
- Voltage Source via V_{SPLIT} Pin for Stabilizing the Recessive Bus Level (Further EMC Improvement)
- Ideal Passive Behavior when Supply Voltage is Removed
- Extremely Low Current Standby Mode
- Compatible with the ISO 11898 Standard (ISO 11898-2, ISO 11898-5 and SAE J2284)
- High Speed (up to 1 Mbps)
- Ideally Suited for 12 V and 24 V Industrial and Automotive Applications
- Extremely Low Current Standby Mode with Wake-up via the Bus
- Low EME Common-Mode Choke is No Longer Required
- Differential Receiver with Wide Common-Mode Range (± 35 V) for High EMS
- Transmit Data (TxD) Dominant Time-out Function
- Thermal Protection
- Bus Pins Protected against Transients in an Automotive Environment
- Power Down Mode in which the Transmitter is Disabled
- Bus and V_{SPLIT} Pins Short Circuit Proof to Supply Voltage and Ground
- Logic Level Inputs Compatible with 3.3 V Devices
- These are Pb-Free Devices

T _{stg}	Storage Temperature		-55	+150	°C
T _{amb}	Ambient Temperature		-40	+125	°C
T _J	Maximum Junction Temperature		-40	+170	°C

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

1. Applied transient waveforms in accordance with ISO 7637 part 3, test pulses 1, 2, 3a, and 3b (see Figure 5).
2. Standardized human body model electrostatic discharge (ESD) pulses in accordance to MIL883 method 3015.7.
3. Static latch-up immunity: Static latch-up protection level when tested according to EIA/JESD78.
4. Standardized charged device model ESD pulses when tested according to EOS/ESD DS5.3-1993.

Table 4. THERMAL CHARACTERISTICS

Symbol	Parameter	Conditions	Value	Unit
R _{th} (vj-a)	Thermal Resistance from Junction-to-Ambient in SOIC-8 Package	In free air	145	K/W
R _{th} (vj-s)	Thermal Resistance from Junction-to-Substrate of Bare Die	In free air	45	K/W

FUNCTIONAL DESCRIPTION

AMIS-42665 provides two modes of operation as illustrated in Table 5. These modes are selectable through pin STB.

Table 5. OPERATING MODES

Mode	Pin STB	Pin RXD	
		Low	High
Normal	Low	Bus Dominant	Bus Recessive
Standby	High	Wake-up Request Detected	No Wake-up Request Detected

Normal Mode

In the normal mode, the transceiver is able to communicate via the bus lines. The signals are transmitted and received to the CAN controller via the pins TxD and RxD. The slopes on the bus lines outputs are optimized to give extremely low EME.

Standby Mode

In standby mode both the transmitter and receiver are disabled and a very low-power differential receiver monitors the bus lines for CAN bus activity. The bus lines are terminated to ground and supply current is reduced to a minimum, typically 10 μ A. When a wake-up request is

detected by the low-power differential receiver, the signal is first filtered and then verified as a valid wake signal after a time period of t_{dbus} , the RxD pin is driven low by the transceiver to inform the controller of the wake-up request.

Split Circuit

The V_{SPLIT} Pin is operational only in normal mode. In standby mode this pin is floating. The V_{SPLIT} is connected as shown in Figure 2 and its purpose is to provide a stabilized DC voltage of $0.5 \times V_{CC}$ to the bus avoiding possible steps in the common-mode signal therefore reducing EME. These unwanted steps could be caused by an unpowered node on the network with excessive leakage current from the bus that shifts the recessive voltage from its nominal $0.5 \times V_{CC}$ voltage.

Wake-up

When a valid wake-up (dominant state longer than t_{dbus}) is received during the standby mode the RxD pin is driven low. Wake-up behavior in case of a permanent dominant – due to, for example, a bus short – represents the only difference between the circuit sub-versions listed in the Ordering Information table. It is depicted in Figures 3 and 4. When the standby mode is entered while a dominant is present on the bus, the “unconditioned bus wake-up” versions will signal a bus-wakeup immediately after the state transition (seen as a High-level glitch on RxD). The other version (differing purely by a metal-level modification in the digital part) will signal bus-wakeup only after the initial dominant is released. In this way it's ensured, that a CAN bus can be put to a low-power mode even if the nodes have a level sensitivity to RxD pin and a permanent dominant is present on the bus.

Overtemperature Detection

A thermal protection circuit protects the IC from damage by switching off the transmitter if the junction temperature exceeds a value of approximately 160°C . Because the transmitter dissipates most of the power, the power dissipation and temperature of the IC is reduced. All other IC functions continue to operate. The transmitter off-state resets when Pin TxD goes high. The thermal protection circuit is particularly needed when a bus line short circuits.

TxD Dominant Time-out Function

A TxD dominant time-out timer circuit prevents the bus lines being driven to a permanent dominant state (blocking all network communication) if Pin TxD is forced permanently low by a hardware and/or software application failure. The timer is triggered by a negative edge on pin TxD. If the duration of the low-level on Pin TxD exceeds the internal timer value $t_{dom}(TxD)$, the transmitter is disabled, driving the bus into a recessive state. The timer is reset by a positive edge on Pin TxD. See Figure 10.

This TxD dominant time-out time ($t_{dom}(TxD)$) defines the minimum possible bit rate to 40 kbps.

Fail Safe Features

A current-limiting circuit protects the transmitter output stage from damage caused by accidental short circuit to either positive or negative supply voltage, although power dissipation increases during this fault condition.

The pins CANH and CANL are protected from automotive electrical transients (according to ISO 7637; see Figure 5). Pins TxD and STB are pulled high internally should the input become disconnected. Pins TxD, STB and RxD will be floating, preventing reverse supply should the V_{CC} supply be removed.

*Even if bus dominant signals longer than t_{dbus} are echoed on RxD, the transceiver stays in standby mode until STB is released.

Figure 3. AMIS42665TJAA1/3 Wake-up Behavior

*On this derivative, bus dominant signals longer than t_{dbus} are echoed on RxD after the bus passed through a recessive time following the trigger of STB. The transceiver stays in standby mode until STB is released.

Figure 4. AMIS42665TJAA6 Wake-up Behavior

ELECTRICAL CHARACTERISTICS

Definitions

All voltages are referenced to GND (Pin 2). Positive currents flow into the IC. Sinking current means the current

is flowing into the pin; sourcing current means the current is flowing out of the pin.

CHARACTERISTICS $V_{CC} = 4.75\text{ V to }5.25\text{ V}$; $T_J = -40^{\circ}\text{C to }+150^{\circ}\text{C}$; $R_{LT} = 60\ \Omega$ unless specified otherwise.

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
--------	-----------	------------	-----	-----	-----	------

SUPPLY (PIN V_{CC})

I_{CC}	Supply Current	Dominant; $V_{TxD} = 0\text{ V}$ Recessive; $V_{TxD} = V_{CC}$		45 4	65 8	mA
I_{CCS}	Supply Current in Standby Mode	$T_{J,max} = 100^{\circ}\text{C}$		10	15	μA

TRANSMITTER DATA INPUT (PIN TxD)

V_{IH}	High-Level Input Voltage	Output Recessive	2.0	–	$V_{CC} + 0.3$	V
V_{IL}	Low-Level Input Voltage	Output Dominant	–0.3	–	+0.8	V
I_{IH}	High-Level Input Current	$V_{TxD} = V_{CC}$	–5	0	+5	μA
I_{IL}	Low-Level Input Current	$V_{TxD} = 0\text{ V}$	–75	–200	–350	μA
C_i	Input Capacitance	Not Tested	–	5	10	pF

TRANSMITTER MODE SELECT (PIN STB)

V_{IH}	High-Level Input Voltage	Standby Mode	2.0	–	$V_{CC} + 0.3$	V
V_{IL}	Low-Level Input Voltage	Normal Mode	–0.3	–	+0.8	V
I_{IH}	High-Level Input Current	$V_{STB} = V_{CC}$	–5	0	+5	μA
I_{IL}	Low-Level Input Current	$V_{STB} = 0\text{ V}$	–1	–4	–10	μA
C_i	Input Capacitance	Not Tested	–	5	10	pF

RECEIVER DATA OUTPUT (PIN RxD)

I_{oh}	High-Level Output Current	$V_o = 0.7 \times V_{CC}$	–5	–10	–15	mA
I_{ol}	Low-Level Output Current	$V_o = 0.3 \times V_{CC}$	5	10	15	mA

BUS LINES (PINS $CANH$ AND $CANL$)
