

Integrated Circuits Group

LRS1383

Stacked Chip 32M Flash and 8M SRAM

(Model No.: LRS1383)

Spec No.: MFM2-J13207 Issue Date: March 1, 2001

- Handle this document carefully for it contains material protected by international copyright law. Any reproduction, full or in part, of this material is prohibited without the express written permission of the company.
- When using the products covered herein, please observe the conditions written herein and the precautions outlined in the following paragraphs. In no event shall the company be liable for any damages resulting from failure to strictly adhere to these conditions and precautions.
 - (1) The products covered herein are designed and manufactured for the following application areas. When using the products covered herein for the equipment listed in Paragraph (2), even for the following application areas, be sure to observe the precautions given in Paragraph (2). Never use the products for the equipment listed in Paragraph (3).
 - Office electronics
 - Instrumentation and measuring equipment
 - Machine tools
 - Audiovisual equipment
 - Home appliance
 - Communication equipment other than for trunk lines
 - (2) Those contemplating using the products covered herein for the following equipment which demands high reliability, should first contact a sales representative of the company and then accept responsibility for incorporating into the design fail-safe operation, redundancy, and other appropriate measures for ensuring reliability and safety of the equipment and the overall system.
 - Control and safety devices for airplanes, trains, automobiles, and other transportation equipment
 - Mainframe computers
 - Traffic control systems
 - Gas leak detectors and automatic cutoff devices
 - Rescue and security equipment
 - Other safety devices and safety equipment, etc.
 - (3) Do not use the products covered herein for the following equipment which demands extremely <u>high performance</u> in terms of functionality, reliability, or accuracy.
 - Aerospace equipment
 - Communications equipment for trunk lines
 - Control equipment for the nuclear power industry
 - Medical equipment related to life support, etc.
 - (4) Please direct all queries and comments regarding the interpretation of the above three Paragraphs to a sales representative of the company.
- Please direct all queries regarding the products covered herein to a sales representative of the company.

1. Description

The LRS1383 is a combination memory organized as 2,097,152 x16 bit flash memory and 524.288 x16 bit static RAM in one package.

Features			
- Power supply	• • • •	2.7V to 2	3.3V
- Operating temperature	• • • •	-25°C to	+85°C
- Not designed or rated as radiation hardened			
- 72pin CSP (LCSP072-P-0811) plastic package			
- Flash memory has P-type bulk silicon, and SRAM has F	-type bulk silic	on	
Flash Memory			
- Access Time	• • • •	85 ns	(Max.)
- Power supply current (The current for F-V_{CC} pin and F-	V _{PP} pin)		
Read	• • • •	25 mA	(Max. t _{CYCLE} = 200ns, CMOS Input)
Word write	• • • •	60 mA	(Max.)
Block erase	• • • •	30 mA	(Max.)
Reset Power-Down	• • • •	25 μΑ	(Max. $F-\overline{RST} = GND \pm 0.2V$,
			$I_{OUT} (F-RY/\overline{BY}) = 0mA)$
Standby	• • • •	25 μΑ	(Max. $F-\overline{CE} = F-\overline{RST} = F-V_{CC} \pm 0.2V$)
- Optimized Array Blocking Architecture			
Eight 4K-word Parameter Blocks			
Sixty-Three 32K-word Main Blocks			
Bottom Parameter Location			
- Extended Cycling Capability		、 、	
	= 2.7 V to 3.3 V		
1,000 Block Erase Cycles and total 80 hours (F- V_{PP}	= 11.7 v to 12.3	3V)	
- Enhanced Automated Suspend Options			
Word Write Suspend to Read			
Block Erase Suspend to Word Write Block Erase Suspend to Read			
- OTP Block 4 Word + 4 Word Array			
SRAM			
- Access Time	• • • •	70 ns	(Max.)
- Power Supply current			
Operating current	• • • •	50 mA	(Max. t_{RC} , t_{WC} = Min.)
	• • • •	8 mA	(Max. t_{RC} , $t_{WC} = 1 \mu s$, CMOS Input)
Standby current	• • • •	25 μΑ	(Max.)
Data retention current	• • • •	25 μΑ	$(Max. S-V_{CC} = 3.0V)$
1			

2. Pin Configuration

Note) From T1 to T3 pins are needed to be open. Two NC pins at the corner are connected. Do not float any GND pins.

Pin	Description	Туре				
A ₀ to A ₁₆ , A ₁₈	Address Inputs (Common)	Input				
F-A ₁₇ , F-A ₁₉ , F-A ₂₀	F-A ₂₀ Address inputs (Flash)					
S-A ₁₇	Address Input (SRAM)	Input				
F-CE	Chip Enable Inputs (Flash)	Input				
$S-\overline{CE}_1$, $S-CE_2$	Chip Enable Inputs (SRAM)					
F-WE	Write Enable Input (Flash)	Input				
S-WE	Write Enable Input (SRAM)	Input				
F-OE	Output Enable Input (Flash)	Input				
S-OE	Output Enable Input (SRAM)	Input				
S- <u>LB</u>	SRAM Byte Enable Input (DQ_0 to DQ_7)	Input				
S-UB	SRAM Byte Enable Input (DQ ₈ to DQ ₁₅)	Input				
F-RST	$\overline{T} = \begin{cases} \text{Reset Power Down Input (Flash)} \\ \text{Block erase and Write : } V_{IH} \\ \text{Read : } V_{IH} \\ \text{Reset Power Down : } V_{IL} \end{cases}$					
F-WP	Write Protect Input (Flash) When F-WP is V _{IL} , locked-down blocks cannot be unlocked. Erase or program operation can be executed to the blocks which are not locked and locked-down. When F-WP is V _{IH} , lock-down is disabled.					
F-RY/BY	Ready/Busy Output (Flash) During an Erase or Write operation : V _{OL} Block Erase and Write Suspend : High-Z (High impedance)	Open Drain Output				
DQ_0 to DQ_{15}	Data Inputs and Outputs (Common)	Input / Output				
F-V _{CC}	Power Supply (Flash)	Power				
S-V _{CC}	Power Supply (SRAM)	Power				
F-V _{PP}	Monitoring Power Supply Voltage (Flash)					
GND	GND (Common)	Power				
NC	Non Connection (Should be all open)	-				
T_1 to T_3	Test pins (Should be all open)	_

Notes:

1. $L = V_{IL}$, $H = V_{IH}$, X = H or L. High-Z = High impedance. Refer to the DC Characteristics.

2. Command writes involving block erase, full chip erase, (page buffer) program or OTP program are reliably executed when $F-V_{PP} = V_{PPH1/2}$ and $F-V_{CC} = 2.7V$ to 3.3V. Block erase, full chip erase, (page buffer) program or OTP program with $F-V_{PP} < V_{PPH1/2}$ (Min.) produce spurious results and should not be attempted.

- 3. Never hold $F-\overline{OE}$ low and $F-\overline{WE}$ low at the same timing.
- 4. Refer Section 5. Command Definitions for Flash Memory valid D_{IN} during a write operation.
- 5. F- \overline{WP} set to V_{IL} or V_{IH}.
- 6. Electricity consumption is lowest when $F-\overline{RST} = GND \pm 0.2V$.
- 7. Flash Read Mode

Mode	Address	DQ_0 to DQ_{15}		
Read Array	Х	D _{OUT}		
Read Identifier Codes/OTP	See 5.2, 5.3	See 5.2, 5.3		
Read Query	Refer to the Appendix	Refer to the Appendix

Н	L	High-Z	D _{OUT} /D _{IN}						

		THEN THE MODES ALLOWED IN THE OTHER PARTITION IS:									
IF ONE PARTITION IS:	Read Array	Read ID/OTP	Read Status	Read Query	Word Program	Page Buffer Program	OTP Program	Block Erase	Full Chip Erase	Program Suspend	
Read Array	Х	X	Х	Х	Х	X		Х		X	X
Read ID/OTP	Х	Х	Х	Х	X	X		Х		X	Х
Read Status	Х	X	Х	Х	Х	X	Х	Х	Х	X	Х
Read Query	Х	Х	Х	Х	Х	X		Х		X	X
Word Program	Х	Х	Х	Х							X
Page Buffer Program	Х	Х	Х	Х							Х
OTP Program			Х								
Block Erase	Х	Х	Х	Х							
Full Chip Erase			Х								
Program Suspend	Х	Х	Х	Х							Х
Block Erase Suspend	Х	Х	Х	Х	X	Х				Х	

Notes:

1. "X" denotes the operation available.

2. Configurative Partition Dual Work Restrictions:

Status register reflects partition state, not WSM (Write State Machine) state - this allows a status register for each partition. Only one partition can be erased or programmed at a time - no command queuing except page buffer program. Commands must be written to an address within the block targeted by that command.

7

5. Command Definitions for Flash Memory⁽¹¹⁾

5.1 Command Definitions

	Bus		F	irst Bus Cycl	e	Second Bus Cycle		
Command	Cycles Req'd	2		Address ⁽²⁾	Data ⁽³⁾	Oper ⁽¹⁾	Address ⁽²⁾	Data ⁽³⁾
Read Array	1	2	Write	PA	FFH			
Read Identifier Codes/OTP	≥2	2,3,4	Write	PA	90H	Read	IA or OA	ID or OD
Read Query	≥2	2,3,4	Write	PA	98H	Read	QA	QD
Read Status Register	2	2,3	Write	PA	70H	Read	PA	SRD
Clear Status Register	1	2	Write	PA	50H			
Block Erase	2	2,3,5	Write	BA	20H	Write	BA	D0H

Block Erase and (Page Buffer) Program Resume	1	2,8,9	Write	PA	D0H			
Set Block Lock Bit	2	2	Write	BA	60H	Write	BA	01H
Clear Block Lock Bit	2	2,10	Write	BA	60H	Write	BA	D0H
Set Block Lock-down Bit	2	2	Write	BA	60H	Write	BA	2FH
OTP Program	2	2,3,9	Write	OA	C0H	Write	OA	OD
Set Partition Configuration Register	2	2,3	Write	PCRC	60H	Write	PCRC	04H

Notes:

1. Bus operations are defined in 3.1 Bus operation.

2. First bus cycle command address should be the same as the second cycle address.

X=Any valid address within the device.

PA=Address within the selected partition.

IA=Identifier codes address (See 5.2, 5.3).

QA=Query codes address. Refer to the LH28F320BX, LH28F640BX series Appendix for details.

BA=Address within the block being erased, set/cleared block lock bit or set block lock-down bit.

WA=Address of memory location for the Program command or the first address for the Page Buffer Program command. OA=Address of OTP block to be read or programmed (See 5.4 OTP Block Address Map).

PCRC=Partition configuration register code presented on the address A0-A15.

3. ID=Data read from identifier codes. (See 5.2, 5.3).

QD=Data read from query database. Refer to the LH28F320BX, LH28F640BX series Appendix for details. SRD=Data read from status register. See 6. Status Register Definition for a description of the status register bits. WD=Data to be programmed at location WA. Data is latched on the rising edge of F-WE or F-CE (whichever goes high first).

OD=Data to be programmed at location OA. Data is latched on the rising edge of $F-\overline{WE}$ or $F-\overline{CE}$ (whichever goes high first).

N-1=N is the number of the words to be loaded into a page buffer.

- 4. Following the Read Identifier Codes/OTP command, read operations access manufacturer code, device code, block lock configuration code, partition configuration register code and the data within OTP block (See 5.2, 5.3). The Read Query command is available for reading CFI (Common Flash Interface) information.
- 5. Block erase, full chip erase or (page buffer) program cannot be executed when the selected block is locked. Unlocked block can be erased or programmed when $F-\overline{RST}$ is V_{IH} .

- 6. Either 40H or 10H are recognized by the CUI (Command User Interface) as the program setup.
- 7. Following the third bus cycle, inputs the program sequential address and write data of "N" times. Finally, input the any valid address within the target partition to be programmed and the confirm command (D0H). Refer to the LH28F320BX, LH28F640BX series Appendix for details.
- 8. If the program operation in one partition is suspended and the erase operation in other partition is also suspended, the suspended program operation should be resumed first, and then the suspended erase operation should be resumed next.
- 9. Full chip erase and OTP program operations can not be suspended. The OTP Program command can not be accepted while the block erase operation is being suspended.
- 10. Following the Clear Block Lock Bit command, block which is not locked-down is unlocked when $F-\overline{WP}$ is V_{IL} . When $F-\overline{WP}$ is V_{IH} , lock-down bit is disabled and the selected block is unlocked regardless of lock-down configuration.
- 11. Commands other than those shown above are reserved by SHARP for future device implementations and should not be used.

	Code	Address $[A_{15}-A_0]^{(1)}$	Data [DQ ₁₅ -DQ ₀]	Notes
Manufacturer Code	Manufacturer Code	0000H	00B0H	
Device Code	32M Bottom Parameter Device Code	0001H	00B5H	2
	Block is Unlocked		$DQ_0 = 0$	3
	Block is Locked	Block Address	$DQ_0 = 1$	3
Block Lock Configuration Code	Block is not Locked-Down	+ 2	$DQ_1 = 0$	3
	Block is Locked-Down		$DQ_1 = 1$	3
Device Configuration Code	Partition Configuration Register	0006H	PCRC	4
OTP	OTP Lock	0080H	OTP-LK	5
OIF	OTP	0081-0088H	OTP	6

Notes:

1. The address A₂₀-A₁₆ to read the manufacturer, device, lock configuration, device configuration code and OTP data are shown in below table.

2. Bottom parameter device has its parameter blocks in the plane 0 (The lowest address).

- 3. DQ_{15} - DQ_2 is reserved for future implementation.
- 4. PCRC=Partition Configuration Register Code.
- 5. OTP-LK=OTP Block Lock configuration.
- 6. OTP=OTP Block data.

5.3 Identifier Codes and OTP Address for Read Operation on Partition Configuration⁽¹⁾

Partit	ion Configuration Re	gister	Address (32M-bit device)
PCR.10	PCR.9	PCR.8	[A ₂₀ -A ₁₆]
0	0	0	00H
0	0	1	00H or 08H
0	1	0	00H or 10H
1	0	0	00H or 18H
0	1	1	00H or 08H or 10H
1	1	0	00H or 10H or 18H
1	0	1	00H or 08H or 18H
1	1	1	00H or 08H or 10H or 18H

Notes:

1. The address to read the identifier codes or OTP data is dependent on the partition which is selected when writing the Read Identifier Codes/OTP command (90H).

OTP Block Address Map for OTP Program (The area outside 80H - 88H cannot be used.)

5.5 Functions of Block Lock⁽¹⁾ and Block Lock-Down

		Cu	rrent State		(3)
State	F-WP	DQ1 ⁽²⁾	DQ ₀ ⁽²⁾	State Name	Erase/Program Allowed ⁽³⁾
[000]	0	0	0	Unlocked	Yes
[001] ⁽⁴⁾	0	0	1	Locked	No
[011]	0	1	1	Locked-down	No
[100]	1	0	0	Unlocked	Yes
[101] ⁽⁴⁾	1	0	1	Locked	No
[110] ⁽⁵⁾	1	1	0	Lock-down Disable	Yes
[111]	1	1	1	Lock-down Disable	No

Note:

1. OTP (One Time Program) block has the lock function which is different from those described above.

2. $DQ_0 = 1$: a block is locked; $DQ_0 = 0$: a block is unlocked.

 $DQ_1 = 1$: a block is locked-down; $DQ_1 = 0$: a block is not locked-down.

3. Erase and program are general terms, respectively, to express: block erase, full chip erase and (page buffer) program operations.

4. At power-up or device reset, all blocks default to locked state and are not locked-down, that is, [001] (F- $\overline{WP} = 0$) or [101] (F- $\overline{WP} = 1$), regardless of the states before power-off or reset operation.

5. When $F-\overline{WP}$ is driven to V_{IL} in [110] state, the state changes to [011] and the blocks are automatically locked.

5.6 Block	Locking S	State Trans	itions upor	Command Write ⁽⁴⁾		
	Curren	t State		Result afte	er Lock Command Written (N	Next State)
State	F-WP	DQ_1	DQ ₀	Set Lock ⁽¹⁾	Clear Lock ⁽¹⁾	Set Lock-down ⁽¹⁾
[000]	0	0	0	[001]	No Change	[011] ⁽²⁾
[001]	0	0	1	No Change ⁽³⁾	[000]	[011]
[011]	0	1	1	No Change	No Change	No Change
[100]	1	0	0	[101]	No Change	[111] ⁽²⁾
[101]	1	0	1	No Change	[100]	[111]
[110]	1	1	0	[111]	No Change	[111] ⁽²⁾
[111]	1	1	1	No Change	[110]	No Change

5.6 Block Locking State Transitions upon Command Write⁽⁴⁾

Note:

1. "Set Lock" means Set Block Lock Bit command, "Clear Lock" means Clear Block Lock Bit command and "Set Lockdown" means Set Block Lock-Down Bit command.

2. When the Set Block Lock-Down Bit command is written to the unlocked block ($DQ_0 = 0$), the corresponding block is locked-down and automatically locked at the same time.

3. "No Change" means that the state remains unchanged after the command written.

4. In this state transitions table, assumes that $F-\overline{WP}$ is not changed and fixed V_{IL} or V_{IH} .

		Current	State		Result after F-WP Tr	cansition (Next State)
Previous State	State	F-WP	DQ ₁	DQ ₀	$F-\overline{WP} = 0 \rightarrow 1^{(1)}$	$F-\overline{WP} = 1 \rightarrow 0^{(1)}$
-	[000]	0	0	0	[100]	-
-	[001]	0	0	1	[101]	-
[110] ⁽²⁾	[011] 0 1		1	[110]	-	
Other than $[110]^{(2)}$	[011]	0	1	1	[111]	-
-	[100]	1	0	0	-	[000]
-	[101]	1	0	1	-	[001]
-	[110]	1	1	0	-	[011] ⁽³⁾
-	[111]	1	1	1	-	[011]

5.7 Block Locking State Transitions upon F-WP Transition⁽⁴⁾

Note:

1. "F- $\overline{WP} = 0 \rightarrow 1$ " means that F- \overline{WP} is driven to V_{IH} and "F- $\overline{WP} = 1 \rightarrow 0$ " means that F- \overline{WP} is driven to V_{IL}

2. State transition from the current state [011] to the next state depends on the previous state.

3. When F- \overline{WP} is driven to V_{IL} in [110] state, the state changes to [011] and the blocks are automatically locked.

4. In this state transitions table, assumes that lock configuration commands are not written in previous, current and next state.

6. Status Register Definition

8. Absolute Maximum Ratings

Symbol	Parameter	Notes	Ratings	Unit
V _{CC}	Supply voltage	1,2	-0.2 to +3.9	V
V _{IN}	Input voltage	1,2,3,4	-0.2 to V _{CC} +0.3	V
T _A	Operating temperature		-25 to +85	°C
T _{STG}	Storage temperature		-55 to +125	°C
F-V _{PP}	F-V _{PP} voltage	1,3,5	-0.2 to +12.6	V

Notes:

- 1. The maximum applicable voltage on any pins with respect to GND.
- 2. Except F-V_{PP}.
- 3. -2.0V undershoot and V_{CC} +2.0V overshoot are allowed when the pulse width is less than 20 nsec.
- 4. V_{IN} should not be over V_{CC} +0.3V.
- Applying 12V ±0.3V to F-V_{PP} during erase/write can only be done for a maximum of 1000 cycles on each block.
 F-V_{PP} may be connected to 12V ±0.3V for total of 80 hours maximum. +12.6V overshoot is allowed when the pulse width is less than 20 nsec.

9. Recommended DC Operating Conditions

 $(T_A = -25^{\circ}C \text{ to } +85^{\circ}C)$

Symbol	Parameter	Notes	Min.	Тур.	Max.	Unit
V _{CC}	Supply Voltage	3	2.7	3.0	3.3	V
V _{IH}	Input Voltage		VCC -0.4 ⁽²⁾		VCC +0.2 ⁽¹⁾	V
V _{IL}	Input Voltage		-0.2		0.4	V

Notes:

1. V_{CC} is the lower of F-V_{CC} or S-V_{CC}.

2. V_{CC} is the higher of F-V_{CC} or S-V_{CC}.

3. V_{CC} includes both F-V_{CC} and S-V_{CC}.

10. Pin Capacitance⁽¹⁾

 $(T_A = 25^{\circ}C, f = 1MHz)$

Symbol	Parameter	Notes	Min.	Тур.	Max.	Unit	Condition

I _{CC1}	S-V _{CC} Operation Current				50	mA	$ \begin{array}{l} S-\overline{CE}_1=V_{IL},\\ S-CE_2=V_{IH}\\ V_{IN}=V_{IL} \text{ or } V_{IH} \end{array} \hspace{0.5cm} t_{CYCL}=Min\\ I_{I/O}=0mA \end{array} $			
I _{CC2}	S-V _{CC} Operation Current				8	mA	$ \begin{array}{l} S \overline{\text{CE}}_1 \leq 0.2 \text{V}, \\ S \overline{\text{CE}}_2 \geq S \overline{\text{-V}}_{\text{CC}} - 0.2 \text{V}, \\ V_{\text{IN}} \geq S \overline{\text{-V}}_{\text{CC}} - 0.2 \text{V} \\ \text{or} \leq 0.2 \text{V} \end{array} \right t_{\text{I/O}} = 0 \text{mA} $			
V _{IL}	Input Low Voltage	6	-0.2		0.4	V				
V _{IH}	Input High Voltage	6	Vcc -0.4		VCC +0.2	v				
V _{OL}	Output Low Voltage	6			0.4	V	$I_{OL} = 0.5 \text{mA}$			
V _{OH}	Output High Voltage	6	V _{CC} -0.2			v	$I_{OH} = -0.5 mA$			
V _{PPLK}	F-V _{PP} Lockout during Normal Operations	4,6,7			0.4	v				
V _{PPH1}	F-V _{PP} during Block Erase, Full Chip		1.65	3	3.3	V				
V _{PPH2}	Erase, Word Write or Lock-Bit configuration Operations	7	11.7	12	12.3	V				
V _{LKO}	F-V _{CC} Lockout Voltage		1.5			V				

Notes:

1. V_{CC} includes both F-V_{CC} and S-V_{CC}.

- 2. All currents are in RMS unless otherwise noted. Typical values at nominal V_{CC} voltage and T_A =+25°C.
- 3. I_{CCWS} and I_{CCES} are specified with the device de-selected. If read or (page buffer) program while in block erase suspend mode, the device's current draw is the sum of I_{CCWS} or I_{CCES} and I_{CCR} or I_{CCW}, respectively.
- Block erase, full chip erase, (page buffer) program and OTP program are inhibited when F-V_{PP} ≤ V_{PPLK}, and not guaranteed in the range between V_{PPLK} (max.) and V_{PPH1} (min.), between V_{PPH1} (max.) and V_{PPH2} (min.) and above V_{PPH2} (max.).
- 5. The Automatic Power Savings (APS) feature automatically places the device in power save mode after read cycle completion. Standard address access timings (t_{AVOV}) provide new data when addresses are changed.
- 6. Sampled, not 100% tested.
- F-V_{PP} is not used for power supply pin. With F-V_{PP} ≤ V_{PPLK}, block erase, full chip erase, (page buffer) program and OTP program cannot be executed and should not be attempted.

Applying $12V \pm 0.3V$ to F-V_{PP} provides fast erasing or fast programming mode. In this mode, F-V_{PP} is power supply pin and supplies the memory cell current for block erasing and (page buffer) programming. Use similar power supply trace widths and layout considerations given to the V_{CC} power bus.

Applying 12V $\pm 0.3V$ to F-V_{PP} during erase/program can only be done for a maximum of 1000 cycles on each block. F-V_{PP} may be connected to 12V $\pm 0.3V$ for a total of 80 hours maximum.

12. AC Electrical Characteristics for Flash Memory

12.1 AC Test Conditions

Input pulse level	0 V to 2.7 V
Input rise and fall time	5 ns
Input and Output timing Ref. level	1.35 V
Output load	$1TTL + C_L (50pF)$

12.2 Read Cycle

	(T _A	$= -25^{\circ}C t$	o +85°C, F	$V_{\rm CC} = 2.7$	7V to 3.3V)
Symbol	Parameter	Notes	Min.	Max.	Unit
t _{AVAV}	Read Cycle Time		85		ns

t_{WHEH} (t_{EHWH})	$F-\overline{CE}$ ($F-\overline{WE}$) Hold from $F-\overline{WE}$ ($F-\overline{CE}$) High		0		ns
$t_{\rm WHDX}(t_{\rm EHDX})$	Data Hold from $F-\overline{WE}$ ($F-\overline{CE}$) High		0		ns
$t_{\rm WHAX}(t_{\rm EHAX})$	Address Hold from $F-\overline{WE}$ ($F-\overline{CE}$) High		0		ns
$t_{\rm WHWL}(t_{\rm EHEL})$	$\overline{F}-\overline{WE}$ ($\overline{F}-\overline{CE}$) Pulse Width High	5	30		ns
$t_{SHWH} (t_{SHEH})$	$\overline{F}-\overline{WP}$ High Setup to $\overline{F}-\overline{WE}$ ($\overline{F}-\overline{CE}$) Going High	3	0		ns
$t_{VVWH}(t_{VVEH})$	$F-V_{PP}$ Setup to $F-\overline{WE}$ ($F-\overline{CE}$) Going High	3	200		ns
$t_{WHGL}(t_{EHGL})$	Write Recovery before Read		30		ns
t _{QVSL}	F-WP High Hold from Valid SRD, F-RY/BY High - Z	3, 6	0		ns
t _{QVVL}	$F-V_{PP}$ Hold from Valid SRD, $F-RY/\overline{BY}$ High - Z	3, 6	0		ns
$t_{WHR0}(t_{EHR0})$	$F-\overline{WE}$ ($F-\overline{CE}$) High to SR.7 Going "0"	3, 7		t _{AVQV} +40	ns
$t_{WHRL} (t_{EHRL})$	$\overline{F-WE}$ ($\overline{F-CE}$) High to $\overline{F-RY/BY}$ Going Low	3		100	ns

Notes:

- 1. The timing characteristics for reading the status register during block erase, full chip erase, (page buffer) program and OTP program operations are the same as during read-only operations. See the AC Characteristics for read cycle.
- 2. A write operation can be initiated and terminated with either $F-\overline{CE}$ or $F-\overline{WE}$.
- 3. Sampled, not 100% tested.
- Write pulse width (t_{WP}) is defined from the falling edge of F-CE or F-WE (whichever goes low last) to the rising edge of F-CE or F-WE (whichever goes high first). Hence, t_{WP}=t_{WLWH}=t_{ELEH}=t_{WLEH}=t_{ELWH}.
- 5. Write pulse width high (t_{WPH}) is defined from the rising edge of F- \overline{CE} or F- \overline{WE} (whichever goes high first) to the falling edge of F- \overline{CE} or F- \overline{WE} (whichever goes low last). Hence, $t_{WPH}=t_{WHWL}=t_{WHEL}=t_{WHEL}=t_{EHWL}$.
- 6. F-V_{PP} should be held at F-V_{PP}=V_{PPH1/2} until determination of block erase, full chip erase, (page buffer) program or OTP program success (SR.1/3/4/5=0).
- 7. t_{WHR0} (t_{EHR0}) after the Read Query or Read Identifier Codes/OTP command= t_{AVOV} +100ns.
- 8. See 5.1 Command Definitions for valid address and data for block erase, full chip erase, (page buffer) program, OTP program or lock bit configuration.

t _{WHRH2} / t _{EHRH2}	Block Erase Suspend Latency Time to Read	5	-		5	20		5	20	μs
t _{ERES}	Latency Time from Block Erase Resume Command to Block Erase Suspend Command	6	-	500			500			μs

12.4 Block Erase, Full Chip Erase, (Page Buffer) Program and OTP Program Performance⁽⁴⁾

Notes:

1. Typical values measured at T_A =+25°C and nominal voltages. Assumes corresponding lock bits are not set. Subject to change based on device characterization.

- 2. Excludes external system-level overhead.
- 3. Every 16 words data are loaded alternatively into 2 page buffers.
- 4. Sampled, but not 100% tested.
- 5. A latency time is required from writing suspend command (F-WE or F-CE going high) until SR.7 going "1" or F-RY/BY going High-Z.
- 6. If the interval time from a Block Erase Resume command to a subsequent Block Erase Suspend command is shorter than t_{ERES} and its sequence is repeated, the block erase operation may not be finished.

12.5 Flash Memory AC Characteristics Timing Chart

AC Waveform for Single Asynchronous Read Operations from Status Register, Identifier Codes, OTP Block or Query Code

12.6 Reset Operations^(1,2)

		$(T_A = -25^{\circ}C \text{ to } +85^{\circ}C, \text{ F-V}_{CC} = 2.7 \text{ V to } 3.$				
Symbol	Parameter	Notes	Min.	Max.	Unit	
t _{PLPH}	F-RST Low to Reset during Read (F-RST should be low during power-up.)	1, 2, 3	100		ns	
t _{PLRH}	F-RST Low to Reset during Erase or Program	1, 3, 4		22	μs	
t _{VPH}	$F-V_{CC} 2.7V$ to $F-\overline{RST}$ High	1, 3, 5	100		ns	
t _{VHQV}	F-V _{CC} 2.7V to Output Delay	3		1	ms	

Notes:

1. A reset time, t_{PHQV}, is required from the later of SR.7 (F-RY/BY) going "1" (High-Z) or F-RST going high until outputs are valid. See the AC Characteristics - read cycle for t_{PHOV}.

- 2. t_{PLPH} is <100ns the device may still reset but this is not guaranteed.
- 3. Sampled, not 100% tested.
- 4. If F-RST asserted while a block erase, full chip erase, (page buffer) program or OTP program operation is not executing, the reset will complete within 100ns.
- 5. When the device power-up, holding F- $\overline{\text{RST}}$ low minimum 100ns is required after F-V_{CC} has been in predefined range and also has been in stable there.

AC Waveform for Reset Operation

13. AC Electrical Characteristics for SRAM

13.1 AC Test Conditions

Input pulse level	0.4V to 2.2V
Input rise and fall time	5ns
Input and Output timing Ref. level	1.5 V
Output load	$1TTL + C_L (30pF)^{(1)}$

Note:

1. Including scope and socket capacitance.

13.2 Read Cycle

	(T)	$A = -25^{\circ}C$	to +85°C,	$S-V_{CC} = 2.$	7V to 3.3V)
Symbol	Parameter	Notes	Min.	Max.	Unit
t _{RC}	Read Cycle Time		70		ns
t _{AA}	Address access time			70	ns
t _{ACE1}	Chip enable access time $(S - \overline{CE}_1)$			70	ns
t _{ACE2}	Chip enable access time (S-CE ₂)			70	ns
t _{BE}	Byte enable access time			70	ns
t _{OE}	Output enable to output valid			40	ns
t _{OH}	Output hold from address change		10		ns
t _{LZ1}	S- \overline{CE}_1 Low to output active	1	10		ns
t _{LZ2}	S-CE ₂ High to output active	1	10		ns

t _{BLZ}	S- $\overline{\text{UB}}$ or S- $\overline{\text{LB}}$ Low to output active	1	5		ns
t _{HZ1}	S- \overline{CE}_1 High to output in High-Z	1	0	25	ns
t _{HZ2}	S-CE ₂ Low to output in High-Z	1	0	25	ns
t _{OHZ}	S-OE High to output in High-Z	1	0	25	ns
t _{BHZ}	S-UB or S-LB High to output in High-Z	1	0	25	ns

Note:

1. Active output to High-Z and High-Z to output active tests specified for a ±200mV transition from steady state levels into the test load.

13.3 Write Cycle

$(T_A = -25^{\circ}C \text{ to } +85^{\circ}C, \text{ S-V}_{CC} = 2.7 \text{ V to})$					7V to 3.3V
Symbol	Parameter	Notes	Min.	Max.	Unit
t _{WC}	Write cycle time		70		ns
t _{CW}	Chip enable to end of write		60		ns
t _{AW}	Address valid to end of write		60		ns
t _{BW}	Byte select time		55		ns
t _{AS}	Address setup time		0		ns
t _{WP}	Write pulse width		50		ns
t _{WR}	Write recovery time		0		ns
t _{DW}	Input data setup time		30		ns
t _{DH}	Input data hold time		0		ns
t _{OW}	S-WE High to output active	1	5		ns
t _{WZ}	S-WE Low to output in High-Z	1	0	25	ns

Note:

1. Active output to High-Z and High-Z to output active tests specified for a ±200mV transition from steady state levels into the test load.

13.4 SRAM AC Characteristics Timing Chart

Read Cycle Timing Chart

A write begins at the latest transition among $S-CE_1$ going low, $S-CE_2$ going high and $S-\overline{WE}$ going low. A write ends at the earliest transition among $S-CE_1$ going high, $S-CE_2$ going low and $S-\overline{WE}$ going high.

twp is measured from the beginning of write to the end of write.

- 2. tcw is measured from the later of S- \overline{CE} | going low or S-CE 2 going high to the end of write.
- 3. t_{BW} is measured from the time of going low S-UB or low S-LB to the end of write.
- 4. tas is measured from the address valid to beginning of write.
- 5. two is measured from the end of write to the address change. t we applies in case a write ends at S- \overline{CE}_{1} going high, S-CE₂ going low or S-WE going high.
- 6. During this period DQ pins are in the output state, therefore the input signals of opposite phase to the outputs must not be applied.
- 7. If $S-\overline{CE}_1$ goes low or $S-CE_2$ goes high simultaneously with $S-\overline{WE}$ going low or after $S-\overline{WE}$ going low, the outputs remain in high impedance state.
- 8. If S-CE₁ goes high or S-CE₂ goes low simultaneously with S-WE going high or before S-WE going high, the outputs remain in high impedance state.

Write Cycle Timing Chart (S-CE Controlled) Device Address Selection Standby Data Valid $V_{I\!H}$ Address Address Stable Vil twc Vih $S-\overline{CE}1$ Vπ. $t_{AS}^{(4)}$ tcw⁽²⁾ $\underline{twr}^{(5)}$ Vih S-CE2 V_{IL} $\underline{t}_{BW}^{(3)}$ Vih S-UB S-LB Vil Vih S-OE Vil taw twp⁽¹⁾ Vih $S-\overline{WE}$ Vп

Notes:

- A write occurs during the overlap of a low S-CE₁, a high S-CE₂ and a low S-WE.
 A write begins at the latest transition among S-CE₁ going low, S-CE₂ going high and S-WE going low.
 A write ends at the earliest transition among S-CE₁ going high, S-CE₂ going low and S-WE going high.
 twp is measured from the beginning of write to the end of write.
- 2. tcw is measured from the later of $S-\overline{CE}_1$ going low or $S-CE_2$ going high to the end of write.
- 3. t_{BW} is measured from the time of going low S-UB or low S-LB to the end of write.
- 4. tas is measured from the address valid to beginning of write.
- 5. two is measured from the end of write to the address change. t we applies in case a write ends at S- \overline{CE}_{1} going high, S-CE₂ going low or S-WE going high.

15. Notes

This product is a stacked CSP package that a 32M (x16) bit Flash Memory and a 8M (x16) bit SRAM are assembled into.

- Supply Power

Maximum difference (between $F-V_{CC}$ and $S-V_{CC}$) of the voltage is less than 0.3V.

- Power Supply and Chip Enable of Flash Memory and SRAM (F- \overline{CE} , S- \overline{CE}_1 , S- \overline{CE}_2)

S- \overline{CE}_1 should not be "low" and S- CE_2 should not be "high" when F- \overline{CE} is "low" simultaneously.

If the two memories are active together, possibly they may not operate normally by interference noises or data collision on DQ bus.

Both $F-V_{CC}$ and $S-V_{CC}$ are needed to be applied by the recommended supply voltage at the same time expect SRAM data retention mode.

- Power Up Sequence

When turning on Flash memory power supply, keep $F-\overline{RST}$ "low". After $F-V_{CC}$ reaches over 2.7V, keep $F-\overline{RST}$ "low" for more than 100nsec.

- Device Decoupling

The power supply is needed to be designed carefully because one of the SRAM and the Flash Memory is in standby mode when the other is active. A careful decoupling of power supplies is necessary between SRAM and Flash Memory. Note peak current caused by transition of control signals ($F-\overline{CE}$, $S-\overline{CE}_1$, $S-CE_2$).

16. Flash Memory Data Protection

Noises having a level exceeding the limit specified in the specification may be generated under specific operating conditions on some systems. Such noises, when induced onto $F-\overline{WE}$ signal or power supply, may be interpreted as false commands, causing undesired memory updating. To protect the data stored in the flash memory against unwanted writing, systems operating with the flash memory should have the following write protect designs, as appropriate.

The below describes data protection method.

- 1. Protecting data in specific block
 - Any locked block by setting its block lock bit is protected against the data alternation. When $F-\overline{WP}$ is V_{IL} , any lockeddown block by setting its block lock-down bit is protected from lock status changes. By using this function, areas can be defined, for example, program area (locked blocks), and data area (unlocked blocks).
 - For detailed block locking scheme, see Chapter 5. Command definitions for Flash Memory.
- 2. Data Protection through $F-V_{PP}$
 - When the level of F-V_{PP} is lower than V_{PPLK} (lockout voltage), write operation on the flash memory is disabled. All blocks are locked and the data in the blocks are completely write protected.
 - For the lockout voltage, refer to the specification. (See Chapter 11. DC Electrical Characteristics)

■ Data Protection during voltage transition

- 1. Data protection thorough $F-\overline{RST}$
 - When the F-RST is kept low during power up and power down sequence, write operation on the flash memory is disabled, write protecting all blocks.
 - For the details of F-RST control, refer to the specification. (See Chapter 12.6 AC Electrical Characteristics for Flash Memory)

17. Design Considerations

1. Power Supply Decoupling

To avoid a bad effect to the system by flash memory power switching characteristics, each device should have a 0.1μ F ceramic capacitor connected between its F-V_{CC} and GND and between its F-V_{PP} and GND. Low inductance capacitors should be placed as close as possible to package leads.

2. F-V_{PP} Trace on Printed Circuit Boards

Updating the memory contents of flash memories that reside in the target system requires that the printed circuit board designer pay attention to the F- V_{PP} Power Supply trace. Use similar trace widths and layout considerations given to the F- V_{CC} power bus.

3. The Inhibition of Overwrite Operation

Please do not execute reprograming "0" for the bit which has already been programed "0". Overwrite operation may generate unerasable bit.

In case of reprograming "0" to the data which has been programed "1".

- Program "0" for the bit in which you want to change data from "1" to "0".
- Program "1" for the bit which has already been programed "0".

For example, changing data from "1011110110111101" to "1010110110111100" requires "11101111111110" programing.

4. Power Supply

Block erase, full chip erase, word write and lock-bit configuration with an invalid $F-V_{PP}$ (See Chapter 11. DC Electrical Characteristics) produce spurious results and should not be attempted. Device operations at invalid $F-V_{CC}$ voltage (See Chapter 11. DC Electrical Characteristics) produce spurious results and should not be attempted.

A-1 RECOMMENDED OPERATING CONDITIONS

A-1.1 At Device Power-Up

AC timing illustrated in Figure A-1 is recommended for the supply voltages and the control signals at device power-up. If the timing in the figure is ignored, the device may not operate correctly.

Figure A-1. AC Timing at Device Power-Up

For the AC specifications t_{VR} , t_R , t_F in the figure, refer to the next page. See the "AC Electrical Characteristics for Flash Memory" described in specifications for the supply voltage range, the operating temperature and the AC specifications not shown in the next page.

A-1.1.1 Rise and Fall Time

Symbol	Parameter	Notes	Min.	Max.	Unit
t _{VR}	F-V _{CC} Rise Time	1	0.5	30000	μs/V
t _R	Input Signal Rise Time	1, 2		TBD	
t _F	Input Signal Fall Time	1, 2		TBD	

NOTES:

1. Sampled, not 100% tested.

2. This specification is applied for not only the device power-up but also the normal operations. t_R (Max.) and t_F (Max.) for F-RP (F-RST) are TBD.

A-1.2 Glitch Noises

Do not input the glitch noises which are below V_{IH} (Min.) or above V_{IL} (Max.) on address, data, reset, and control signals, as shown in Figure A-2 (b). The acceptable glitch noises are illustrated in Figure A-2 (a).

1 Introduction

This appendix describes how to use the LH28F320BX/ LH28F640BX series, Synchronous/Page Mode Dual Work Flash memory. Section 1 outlines the LH28F320BX/LH28F640BX series. Sections 2, 3, 4 and 5 describe the memory organization and functionality. When designing a specific system, take into design considerations described in Section 5.

1.1 Features

Synchronous/Page Mode Dual Work Flash memory LH28F320BX/LH28F640BX series has the following features:

- Dual work operation
- Flexible partition configuration
- High performance asynchronous reads and synchronous burst reads
- Page buffer program
- Individual block locking and all blocks locked on power-up
- 8-word OTP (One Time Program) block
- Low power consumption
- Parameter block architecture

1.2 Definition of Block, Plane and Partition

Block, Plane and Partition are defined and used in this document as explained below.

- Block
- Main Block: 32K Words.
- Parameter Block: 4K Words.

32M-bit device has 8 parameter blocks and 63 main blocks.

64M-bit device has 8 parameter blocks and 127 main blocks.

- Plane: 32M-bit and 64M-bit devices are divided into four physical planes (see Table 1).
 Plane0 or Plane3 contains parameter blocks and main blocks. Plane1 and Plane2 consist of only main blocks.
- Partition: Read operation can be done in one partition while Program/Erase operation is being done in another partition. Partition contains at least one plane or up to four planes. Partition boundaries can be flexibly set to any plane boundary by the Set Partition Configuration Register command. If the partition configuration register is set to "111" (4 plane dual work mode), the partition is exactly the same as a plane. See Section 4.17 for more information.

Table 1. Address Range of Each Plane

Plane #	Contains the Blocks within the following Address				
	32M bit	64M bit			
Plane 0	000000H-07FFFFH	000000H-0FFFFFH			
Plane 1	080000H-0FFFFFH	100000H-1FFFFFH			
Plane 2	100000H-17FFFFH	200000H-2FFFFFH			
Plane 3	180000H-1FFFFFH	300000H-3FFFFFH			

1.3 Product Overview

Synchronous/Page Mode Dual Work Flash memory LH28F320BX/LH28F640BX series is capable of dual work operation: erase or program operation on one partition and read operation on other partitions (see Table 2). The partition to be accessed is automatically identified according to the input address. Dual work operations can be achieved by dividing the memory array into four physical planes as shown in Figure 2.1 through Figure 3.2. Each plane is exactly one quarter of the entire memory array. The device has also virtual partitions. Several planes can be flexibly merged to one partition by writing the Set Partition Configuration Register command. This feature allows the user to read from one partition even though one of the other partitions is executing an erase or program operation. If the device is set to the 4 partitions configuration, each partition is exactly the same as each physical plane. After power-up or device reset, plane 0-2 are merged into one partition for top parameter devices and plane1-3 are merged into one partition for bottom parameter devices.

During dual work operation, read operations to the partition being erased or programmed access the status register which indicates whether the erase or program operation is successfully completed or not. Dual work operation cannot be executed during full chip erase and OTP program mode.

Memory array data can be read in two ways, that is, asynchronous 8-word page mode or synchronous burst mode. The default after power-up or device reset is the asynchronous read mode in which 8-word page mode is available. The user must set the read configuration register to enable the synchronous burst mode by writing the Set Read Configuration Register command. CLK is then used to increment the internal burst address generator, synchronize with the host, and deliver data every clock cycle. The WAIT# output pin is used to signal

that a burst is in progress. The synchronous burst feature cannot cross partition boundaries.

The LH28F320BX/LH28F640BX series contains a page buffer of 16-word \times 2 plane. In the page buffer program mode, the data to be programmed is first stored into the page buffer before being transferred to the memory array. A page buffer program has high speed program performance. The page buffer program operation programs up to 16 word \times 2 data at sequential addresses within one block. That is, this operation cannot be used to program data at addresses separated by something even in the same block, or divided into different blocks. Page buffer program cannot be applied to OTP block described later in this section.

For the parameter blocks and main blocks, individual block locking scheme that allows any block to be locked, unlocked or locked-down with no latency. The time required for block locking is less than the minimum command cycle time (minimum time from the rising edge of CE# or WE# to write the command to the next rising edge of CE# or WE#). The block is locked via the Set Block Lock Bit command or Set Block Lock-down bit command. Block erase, full chip erase and (page buffer) program operation cannot be executed for locked block, to protect codes and data from unwanted operation due to noises, etc. When the WP# pin is at VIL, the locked-down block cannot be unlocked. When WP# pin is at V_{IH} , lockdown bits are disabled and any block can be locked or unlocked through software. After WP# goes VIL, any block previously marked lock-down revert to that state. At power-up or device reset, all blocks default to locked state and are not locked-down, regardless of the states before power-off or reset operation. This means that all write operations on any block are disabled.

Unauthorized use of cellular phone, communication device, etc. can be avoided by storing a security code into the 8-word OTP (One Time Program) block (see Figure 4) provided in addition to the parameter and main blocks. To ensure high reliability, a lock function for the OTP block is provided.

The LH28F320BX/LH28F640BX series has a V_{PP} pin which monitors the level of the power supply voltage. When $V_{PP} \leq V_{PPLK}$, memory contents cannot be altered and the data in all blocks are completely write protected (see Note 1). Note that the V_{PP} is used only for checking the supply voltage, not used for device power supply pin.

Automatic Power Savings (APS) is the low power features to help increase battery life in portable applications. APS mode is initiated shortly after read cycle completion. In this mode, its current consumption decreases to the value equivalent of that in the standby mode. Standard address access timings (t_{AVQV}) provide new data when addresses are changed. During dual work operation (one partition being erased or programmed, while other partitions are read modes), the device cannot enter the Automatic Power savings mode if the input address remains unchanged.

A CUI (Command User Interface) serves as the interface between the system processor and internal operation of the device. A valid command sequence written to the CUI initiates device automation. LH28F320BX/LH28F640BX series uses an advanced WSM (Write State Machine) to automatically execute erase and program operations within the memory array. The WSM is controlled through the CUI. By writing a valid command sequence to the CUI, the WSM is instructed to automatically handle the sequence of internal events and timings required to block erase, full chip erase, (page buffer) program or OTP program operations.

Status registers are prepared for each partition to indicate the status of the partition. Even if the WSM is occupied by executing erase or program operation in one partition, the status register of other partition reports that the device is not busy when the device is set to 2, 3 or 4 partitions configuration.

When the RST# pin is at V_{IL} , reset mode is enabled which minimizes power consumption and provides write protection. The RST# is also useful for resetting the WSM to read array mode and initializing the status register bits to "80H". During power-on/off or transitions, keep the RST# pin at V_{IL} level to protect the data from noises, and initialize the device's internal control circuit.

(Note 1) Please note following:

- For the lockout voltage V_{PPLK} to inhibit all write functions, refer to specifications.
- V_{PP} should be kept lower than V_{PPLK} (GND) during read operations to protect the data in all blocks.

A reset time (t_{PHQV}) is required from RST# switching high until outputs are valid. Likewise, the device has a wake time (t_{PHWL}, t_{PHEL}) from RST#-high until writes to the CUI are recognized.

Erase operation erases one block or all blocks. Programming is executed in either one word increments or by page sized increments using the high speed program page buffers. These operations use an industry standard set of CUI command sequences. Suspend commands exist for both the erase and program operations to permit the system to interrupt an erase or program operation in progress to enable the access to another memory location in the same partition. Nested suspend is also supported. This allows the software to suspend an erase in one partition, start programming in a second partition, suspend programming in the second partition, then read from the second partition. After reading from the second partition, resume the suspended program in the second partition, then resume the suspended erase in the first partition.

Figure 1 shows the block diagram for LH28F320BX/ LH28F640BX series. The example of pin descriptions are explained in Table 3.1 and Table 3.2.

			THEN 1	THE MO	DES ALL	OWED IN	THE OT	HER PAI	RTITION IS	S:

Table 2. Simultaneous Operation Modes Allowed with Four $\mathsf{Planes}^{(1,\,2)}$

NOTES:

1. "X" denotes the operation available.

2. Configurative Partition Dual Work Restrictions:

Status register reflects partition state, not WSM(Write State Machine) state - this allows a status register for each partition. Only one partition can be erased or programmed at a time - no command queuing except page buffer program. Commands must be written to an address within the block targeted by that command. It is not possible to do burst reads that cross partition boundaries.

5

	Table 3.1. Pin Descriptions								
	Symbol	Туре	Name and Function]					
	A ₀ -A ₂₀	INPUT	ADDRESS INPUTS: Inputs for addresses. 32M: A ₀ -A ₂₀						
A ₀ -A ₂₁ INPUT			ADDRESS INPUTS: Inputs for addresses. 64M: A ₀ -A ₂₁						
	DQ ₀ -DQ ₁₅	INPUT/ OUTPUT	DATA INPUT/OUTPUTS: Inputs data and commands during CUI (Command User Interface) write cycles, outputs data during memory array, status register, query, identifier code and device configuration code reads. Data pins float to high-impedance (High Z) when the chip or outputs are deselected. Data is internally latched during an erase or program cycle.						
	CE#	INPUT	Chip Enable: Activates the device's control logic, input buffers, decoders and sense amplifiers. CE#-high (V_{IH}) deselects the device and reduces power consumption to standby levels.						
	CLK INPUT		CLOCK: Synchronizes the memory to the system bus operating frequency in synchronous burst mode. The first rising (or falling if RCR.6 is "0") edge latches the address when ADV# is V_{IL} or upon a rising ADV# edge. This is used only for						
			synchronous burst mode. ADDRESS VALID: Addresses are input to the memory when ADV# is low (V_{II}) .	- I					
	ADV#	INPUT	Addresses are latched on ADV#'s rising edge during read and write operations.						
			RESET: When low (V_{II}) , RST# resets internal automation and inhibits write operations						
	RST#	RST# INPUT	which provides data protection. RST#-high (V_{IH}) enables normal operation. After power-up or reset mode, the device is automatically set to asynchronous read array mode. RST# must be low during power-up.						
	OE#	INPUT	OUTPUT ENABLE: Gates the device's outputs during a read cycle.	1					
	WE#	INPUT	WRITE ENABLE: Controls writes to the CUI and array blocks. Addresses and data are latched on the rising edge of CE# or WE# (whichever goes high first).						
	WP#	INPUT	WRITE PROTECT: When WP# is V_{IL} , locked-down blocks cannot be unlocked. Erase or program operation can be executed to the blocks which are not locked and locked-down. When WP# is V_{IH} , lock-down is disabled.						
	WAIT# OUTPUT		WAIT: Outputs data valid status in synchronous burst mode while OE# is asserted. When high (V_{OH}) during a burst mode, data is valid. WAIT# low (V_{OL}) indicates invalid data. WAIT# is pulled high (V_{OH}) by an internal resister. The WAIT# signals of the multiple devices can be tied together to drive one system WAIT# signal. WAIT# is used only for synchronous burst mode. It also works during a continuous burst mode or 4-, 8-word burst with no-wrap (RCR.3="1") mode						

	Table 3.2. Pin Descriptions (Continued)					
		MONITORING POWER SUPPLY VOLTAGE: V _{PP} is not used for power supply pin.				
		With $V_{PP} \leq V_{PPLK}$, block erase, full chip erase, (page buffer) program or OTP program				
		cannot be executed and should not be attempted.				
V_{PP}	INPUT	Applying $12V\pm0.3V$ to V_{PP} provides fast erasing or fast programming mode. In this				
• PP		mode, V_{PP} is power supply pin. Applying 12V±0.3V to V_{PP} during erase/program can				
		only be done for a maximum of 1000 cycles on each block. VPP may be connected to				
		12V±0.3V for a total of 80 hours maximum. Use of this pin at 12V beyond these limits				
		may reduce block cycling capability or cause permanent damage.				
		DEVICE POWER SUPPLY (see specifications): With $V_{CC} \leq V_{LKO}$, all write attempts to				
V _{CC}	SUPPLY	the flash memory are inhibited. Device operations at invalid V _{CC} voltage (see DC				
		Characteristics) produce spurious results and should not be attempted.				
Vaaa	SUPPLY	INPUT/OUTPUT POWER SUPPLY (see specifications): Power supply for all input/				
V _{CCQ}	SUILI	output pins.				
GND	SUPPLY	GROUND: Do not float any ground pins.				
NC		NO CONNECT: Lead is not internally connected; it may be driven or floated.				

8

1.4 Product Description

1.4.1 Memory Block Organization

The device is divided into four physical planes and the partitions can be flexibly configured by the Set Partition Configuration Register command. This allows dual work operations, that is, simultaneous read-while-erase and read-while-program operations. For the address locations of the blocks, see the memory map in Figure 2.1 through Figure 3.2.

1.4.2 Four Physical Planes

LH28F320BX/LH28F640BX series has four physical planes (one parameter plane and three uniform planes). Each plane consists of 8M-bit (32M-bit device) or 16M-bit (64M-bit device) Flash memory. The parameter plane consists of eight 4K-word parameter blocks and fifteen (32M-bit device) or thirty-one (64M-bit device) 32K-word main blocks. Each uniform plane consists of sixteen (32M-bit device) or thirty-two (64M-bit device) 32K-word main blocks. Each block can be erased independently up to 100,000 times.

1.4.3 Partition

Partition boundaries can be configured by the Set Partition Configuration Register command. Dual work operation can be done in two partitions. See partition configuration in Table 17 and Figure 17 for more detail. Only one partition can be erased or programmed at a time and burst reads cannot cross partition boundaries. Simultaneous operation modes are shown in Table 2.

1.4.4 Parameter Block

Eight 4K-word parameter blocks within the parameter partition are provided as the memory area to facilitate storage of frequently update small parameters that would normally be stored in EEPROM. By using software techniques, the word-rewrite functionality of EEPROMs can be emulated. The protection of the parameter block is controlled using a combination of the V_{PP} RST#, WP#, block lock bit and block lock-down bit.

1.4.5 Main Block

32K-word main blocks can store code and/or data. The protection of the main block is also controlled using a combination of the V_{PP} , RST#, WP#, block lock bit and block lock-down bit.

1.4.6 OTP (One Time Program) block

The OTP block is a special block that cannot be erased in order to secure the high system reliability. This 8-word (128-bit) OTP block is independent of the 32M-bit or 64M-bit memory area. Figure 4 shows the OTP block address map.

The OTP block is divided into two areas. One is a factory programmed area where a unique number has been programmed in SHARP factory. This factory programmed area is "READ ONLY" (already locked). The other is a customer programmable area that can be available for customers. This customer programmable area can also be locked. After locking, this customer programmable area is protected permanently.

The data within the OTP block can be read by the Read Identifier Codes/OTP command (90H). To return to read array mode, write the Read Array command (FFH) to the CUI.

The OTP block bits are programmed by writing the OTP Program command (C0H) to the CUI. Write the OTP Program command (C0H) at the 1st command cycle and then write the address and the data at the 2nd cycle. If the OTP program operation is failed, the status register bit SR.4 is set to "1". If the OTP block is locked, the status register bits SR.4 and SR.1 are set to "1".

The OTP block can be locked using the OTP Program command (C0H). Write the OTP Program command (C0H) at the 1st command cycle and then write the data (FFFDH) to the lock location (80H) at the 2nd cycle. Read cycle from address (80H) indicates the lockout state of the OTP block. Bit 0 of address (80H) means the factory programmed area lock state ("1" is "NOT LOCKED" and "0" is "LOCKED"). Bit 1 of address (80H) means the customer programmable lock state. OTP block lockout state is not reversible. Unlike the main array block lock configuration, the lock state of the OTP block is kept unchanged even if the power is turned off or reset operation is performed.

The OTP Program command is only available for programming the OTP block. Page buffer program operations are available for the main array. OTP program cannot be suspended through the (Page Buffer) Program Suspend command (described later). Dual work operation cannot be executed during OTP program.

Figure 4. OTP Block Address Map for OTP $Program^{(1, 2)}$ (The area outside 80H~88H cannot be used.)

NOTES:

A₂₁ is not used for 32M-bit device.
 Refer to Table 6 through Table 8 as to the OTP block address map for read operation.

2 Principles of Operation

Synchronous/Page Mode Dual Work Flash memory LH28F320BX/LH28F640BX series includes an on-chip WSM (Write State Machine) and can automatically execute block erase, full chip erase, (page buffer) program or OTP program operation after writing the proper command to the CUI (Command User Interface).

2.1 Operation Mode after Power-up or Reset Mode

After initial power-up or reset mode (refer to Bus Operation in Section 3), the device defaults to the following mode.

- Asynchronous read mode in which 8-word page mode is available
- Plane 0-2 are merged into one partition for top parameter devices and plane1-3 are merged into one partition for bottom parameter devices.
- All blocks default to locked state and are not lockeddown.

Manipulation of external memory control pins (CE#, OE#) allow read array, standby and output disable modes.

2.2 Read, Program and Erase Operation

Independent of the V_{PP} voltage, the memory array, status register, identifier codes, OTP block and query codes can be accessed. And also, set/clear block lock configuration, set read configuration register and set partition configuration register are available even if the V_{PP} voltage is lower than V_{PPLK}. Applying the specified voltage on V_{CC} and V_{PPH1/2} on V_{PP} enables successful block erase, full chip erase, (page buffer) program and OTP program operation. All functions associated with altering memory contents, which is block erase, full chip erase, (page buffer) program, are accessed via the CUI and verified through the status register.

Commands are written using standard microprocessor write timings. Addresses and data are internally latched on the rising edge of CE# or WE# whichever goes high first during command write cycles. The CUI contents serve as input to the WSM, which controls block erase, full chip erase, (page buffer) program and OTP program. The internal algorithms are regulated by the WSM, including pulse repetition, internal verification and margining of data. Writing the appropriate command outputs array data, status register data, identifier codes, lock configuration codes, device configuration codes, data within the OTP block and query codes.

In any block, the user can store an interface software that initiates and polls progress of block erase or (page buffer) program. Because the LH28F320BX/LH28F640BX series has dual work function, data can be read from the partition not being erased or programmed without using the block erase suspend or (page buffer) program suspend. When the target partition is being erased or programmed, block erase suspend or (page buffer) program suspend allows system software to read/program data from/to blocks other than that which is suspended.

2.3 Status Register for Each Partition

The LH28F320BX/LH28F640BX series has status registers for each partition. The 8-bit status register is available to monitor the partition state, or the erase or program status. Status Register indicates the status of the partition, not WSM. Even if the status register bit SR.7 is "1", the WSM may be occupied by the other partition when the device is set to 2, 3 or 4 partitions configuration. The status register reports if an erase or program operation to each partition has been successfully completed, and if not, indicates a reason for the error. This register cannot be set, only can be cleared by writing the Clear Status Register command or by resetting the device.

2.4 Data Protection

Block lock bit and block lock-down bit can be set for each block, to protect the data within its block.

If the RST# is driven low (V_{IL}), or if the voltage on the V_{CC} pin is below the write lock out voltage (V_{LKO}), or if the voltage on the V_{PP} pin is below the write lock out voltage (V_{PPLK}), then all write functions including OTP program are disabled.

The system should be designed to switch the voltage on V_{PP} below the write lock out voltage (V_{PPLK}) for read cycles. This scheme provides the data protection at the hardware level. The two-cycle command sequence architecture for block erase, full chip erase, (page buffer) program, OTP program, and block lock configuration provides the data protection at the software level against data alternation.

Rev. 2.20

3 Bus Operation

The system CPU reads and writes the flash memory. All bus cycles to or from the flash memory conform to standard microprocessor bus cycles. Table 4 lists the bus operation.

3.1 Read Array

LH28F320BX/LH28F640BX series has seven control pins (CLK, CE#, OE#, ADV#, WE#, RST# and WP#). When RST# is $V_{\rm IH}$, read operations access the memory array, status register, identifier codes, OTP block and query codes independent of the voltage on $V_{\rm PP}$

The device is automatically initialized upon power-up or device reset mode and set to asynchronous read mode in which 8-word page mode is available. As necessary, write the appropriate read command (Read Array, Read Identifier codes/OTP, Read Query or Read Status Register command) with the partition address to the CUI (Command User Interface). The CUI decodes the partition address and set the target partition to the appropriate read mode.

Synchronous burst mode can be set by writing the Set Read Configuration Register command. It is impossible to set one partition to asynchronous read mode and other partition to synchronous burst mode at a time.

Asynchronous page mode and synchronous burst mode are available only for main array, that is, parameter blocks and main blocks. Read operations for status register, identifier codes, OTP block and query codes support single asynchronous read cycle or single synchronous read cycle.

To read data from the LH28F320BX/LH28F640BX series, RST# and WE# must be at V_{IH} , and CE# and OE# at V_{IL} . ADV# must be driven V_{IL} to fetch address. CE# is the device selection control, and CE#-low enables the selected memory device. OE# is the data output (DQ₀-DQ₁₅) control and OE#-low drives the selected memory data onto the I/O bus.

3.2 Output Disable

With OE# at V_{IH} , the device outputs are disabled. Output pins $DQ_0 - DQ_{15}$ are placed in a high-impedance (High Z) state.

3.3 Standby

CE# at a logic-high level (V_{IH}) places the LH28F320BX/ LH28F640BX series in standby mode.

In standby mode, the LH28F320BX/LH28F640BX series substantially reduces its power consumption because almost of all internal circuits are inactive. DQ_0 - DQ_{15} outputs a High Z state independent of OE#. Even if CE# is set to V_{IH} during block erase, full chip erase, (page buffer) program or OTP program, the device continues the operation and consumes active power until the completion of the operation.

3.4 Reset

Driving RST# to logic-low level (V_{IL}) places the LH28F320BX/LH28F640BX series in reset mode.

If RST# is held V_{IL} for a minimum t_{PLPH} in read modes, the device is deselected and internal circuitry is turned off. Outputs are placed in a High Z state. Status register is set to 80H. Time t_{PHQV} is required after return from reset mode until initial memory access outputs are valid. After this wake-up interval, normal operation is restored. The device returns to the initial mode described in Section 2.1.

During block erase, full chip erase, (page buffer) program or OTP program mode, RST#-low will abort the operation. Memory contents being altered are no longer valid; the data may be partially erased or programmed. Status register bit SR.7 remains "0" until the reset operation has been completed. After RST# goes to V_{IH} , time t_{PHWL} and t_{PHEL} is required before another command can be written.

As with any automated device, it is important to assert RST# during system reset. When the system comes out of reset, it expects to read the data from the flash memory. LH28F320BX/LH28F640BX series allows proper CPU initialization following a system reset through the use of the RST# input. In this application, RST# is controlled by the same RESET# signal that resets the system CPU. After return from reset mode, the LH28F320BX/LH28F640BX series is automatically set to asynchronous read mode in which 8-word page mode is available. Delay time t_{PHQV} is required until memory access outputs are valid.

Table 4. Bus $Operation^{(1, 2)}$

Mode	Notes	RST#	CE#	OE#	WE#	Address	V _{PP}	DQ ₀₋₁₅
Read Array	6	V _{IH}	V _{IL}	V _{IL}	V _{IH}	Х	Х	D _{OUT}
Output Disable		V _{IH}	V _{IL}	V _{IH}	V _{IH}	Х	Х	High Z
Standby		V _{IH}	V _{IH}	Х	Х	Х	Х	High Z
Reset	3	V_{IL}	Х	Х	Х	Х	Х	High Z
Read Identifier Codes/OTP	6	V _{IH}	V _{IL}	V _{IL}	V _{IH}	See Table 6 through Table 8	Х	See Table 6 through Table 8
Read Query	6,7	V _{IH}	V _{IL}	V _{IL}	V _{IH}	See Section 6	Х	See Section 6
Write	4,5,6	V _{IH}	V _{IL}	V _{IH}	V _{IL}	Х	Х	D _{IN}

NOTES:

1. Refer to DC Characteristics. When V_{PP}≤V_{PPLK}, memory contents can be read, but cannot be altered.

2. X can be VIL or VIH for control pins and addresses, and VPPLK or VPPH1/2 for VPP See DC Characteristics for VPPLK and V_{PPH1/2} voltages.

3. RST# at GND±0.2V ensures the lowest power consumption.

4. Command writes involving block erase, full chip erase, (page buffer) program or OTP program are reliably executed when $V_{PP}=V_{PPH1/2}$ and V_{CC} is the specified voltage. 5. Refer to Table 5 for valid D_{IN} during a write operation.

- 6. Never hold OE# low and WE# low at the same timing.

7. Refer to Appendix of LH28F320BX/LH28F640BX series for more information about query code.

3.5 Read Identifier Codes/OTP

The manufacturer code, device code, block lock configuration codes, read configuration register code, partition configuration register code and the data within the OTP block can be read in the read identifier codes/ OTP mode (see Table 6 through Table 8). Using the manufacturer and device codes, the system CPU can automatically match the device with its proper algorithms.

3.6 Read Query

CFI (Common Flash Interface) code, which is called query code, can be read after writing the Read Query command. The address to read query code should be in the partition address which is written with the Read Query command. The CFI data structure contains information such as block size, density, command set and electrical specifications (see Section 6). In this mode, read cycles retrieve CFI information. To return to read array mode, write the Read Array command (FFH) with the partition address.

3.7 Write the Command to the CUI

Except for the Full Chip Erase command, writing commands to the CUI always requires the word address, block address or partition address. Before writing the Block Erase command, Full Chip Erase command, (Page Buffer) Program command or OTP Program command, WSM (Write State Machine) should be ready and not be used in any partition.

Applying the specified voltage on V_{CC} and $V_{PPH1/2}$ on V_{PP} enables successful block erase, full chip erase, (page buffer) program or OTP program with writing the proper command and address to the CUI. Erase or program operation may occur in only one partition at a time. Other partitions must be in one of the read modes.

The Block Erase command requires appropriate command and an address within the block to be erased. The Full Chip Erase command requires appropriate command. The (Page Buffer) Program command requires appropriate command and an address of the location to be programmed. The Set/Clear Block Lock Bit or Set Block Lock-down Bit command requires appropriate command and an address within the target block. The OTP Program command requires appropriate command requires appropriate command and an address of the location to be programmed within the target block. The OTP Program command requires appropriate command and an address of the location to be programmed within the OTP block. The Set Read Configuration Register command or the Set Partition Configuration Register command requires appropriate command and configuration register code presented on the addresses A_0 - A_{15} .

The CUI itself does not occupy an addressable memory location. When both CE# and WE# go V_{IL} (valid), the command is written to CUI and the address and data are latched on the rising edge of CE# or WE#, whichever goes high first. The command can be written to the CUI at the standard microprocessor writing timing.

4 Command Definitions

Operations of the device are selected by the specific commands written to the CUI (Command User Interface). Since commands are partition-specific, it is important to write commands within the target partition's address range (see Table 5).

Each command except for the Full Chip Erase command and OTP Program command affects only the mode of the partition to which the command is written.

4.1 Read Array Command

Upon initial device power-up or after reset mode, all the partitions in the device default to asynchronous read mode in which 8-word page mode is available. The Read Array command to a partition places the partition to read array mode. The partition remains enabled for read array mode until another valid command is written to the partition. When RST# is at VIH, the Read Array command is valid independent of the voltage on V_{PP}. Once the internal WSM (Write State Machine) has started block erase, full chip erase, (page buffer) program or OTP program in one partition, the partition will not recognize the Read Array command until the WSM completes its operation or unless the WSM is suspended via the Block Erase Suspend or (Page Buffer) Program Suspend command. However, the Read Array command can be accepted in other partitions except for full chip erase or OTP program operation.

Since LH28F320BX/LH28F640BX series provide dual work capability, partitions not executing block erase or (page buffer) program operation are allowed to set to the read array mode and the memory array data within the partitions can be read without suspending block erase or (page buffer) program operation.

4.2 Read Identifier Codes/OTP Command

The read identifier codes/OTP mode is initiated by writing the Read Identifier Codes/OTP command (90H) to the target partition. Read operations to that partition output the identifier codes or the data within the OTP block. To terminate the operation, write another valid command to the partition. In this mode, the manufacturer code, device code, block lock configuration codes, read configuration register code, partition configuration register code and the data within the OTP block as well as the OTP block lock state can be read on the addresses shown in Table 6 through Table 8. Once the internal WSM has started block erase, full chip erase, (page buffer) program or OTP program in one partition, the partition will not recognize the Read Identifier Codes/ OTP command until the WSM completes its operation or unless the WSM is suspended via the Block Erase Suspend or (Page Buffer) Program Suspend command. However, the Read Identifier Codes/OTP command can be accepted in other partitions except for full chip erase or OTP program operation. Like the Read Array command, the Read Identifier Codes/OTP command functions independently of the VPP voltage and RST# must be at V_{IH}.

To read the data in the OTP block, it is important to write addresses within the OTP area's address range (refer to Table 6 through Table 8).

Asynchronous page mode and synchronous burst mode are not available for reading identifier codes/OTP. Read operations for identifier codes or OTP block support single asynchronous read cycle or single synchronous read cycle.

Command	Bus	Notes	Ι	First Bus Cyc	le	Se	econd Bus C	ycle

 Cable 5. Command Definitions⁽¹¹⁾

NOTES:

1. Bus operations are defined in Table 4.

2. First bus cycle command address should be the same as the second cycle address.

X=Any valid address within the device.

PA=Address within the selected partition.

IA=Identifier codes address (See Table 6 through Table 8).

QA=Query codes address. Refer to Appendix of LH28F320BX/LH28F640BX series for details.

BA=Address within the block being erased, set/cleared block lock bit or set block lock-down bit.

WA=Address of memory location for the Program command or the first address for the Page Buffer Program command. OA=Address of OTP block to be read or programmed (See Figure 4).

RCRC=Read configuration register code presented on the addresses A_0 - A_{15} .

PCRC=Partition configuration register code presented on the address A_0 - A_{15} .

3. ID=Data read from identifier codes. (See Table 6 through Table 8).

QD=Data read from query database. Refer to Appendix of LH28F320BX/LH28F640BX series for details.

SRD=Data read from status register. See Table 9 for a description of the status register bits.

WD=Data to be programmed at location WA. Data is latched on the rising edge of WE# or CE# (whichever goes high first).

OD=Data to be programmed at location OA. Data is latched on the rising edge of WE# or CE# (whichever goes high first).

N-1=N is the number of the words to be loaded into a page buffer.

4. Following the Read Identifier Codes/OTP command, read operations access manufacturer code, device code, block lock configuration code, read configuration register code, partition configuration register code and the data within OTP block (See Table 6 through Table 8).

The Read Query command is available for reading CFI (Common Flash Interface) information.

- 5. Block erase, full chip erase or (page buffer) program cannot be executed when the selected block is locked. Unlocked block can be erased or programmed when RST# is V_{IH}.
- 6. Either 40H or 10H are recognized by the CUI (Command User Interface) as the program setup.

- 7. Following the third bus cycle, inputs the program sequential address and write data of "N" times. Finally, input the any valid address within the target partition to be programmed and the confirm command (D0H). Refer to Appendix of LH28F320BX/LH28F640BX series for details.
- 8. If the program operation in one partition is suspended and the erase operation in other partition is also suspended, the suspended program operation should be resumed first, and then the suspended erase operation should be resumed next.
- 9. Full chip erase and OTP program operations can not be suspended. The OTP Program command can not be accepted while the block erase operation is being suspended.
- 10. Following the Clear Block Lock Bit command, block which is not locked-down is unlocked when WP# is V_{IL} . When WP# is V_{IH} , lock-down bit is disabled and the selected block is unlocked regardless of lock-down configuration.
- 11. Commands other than those shown above are reserved by SHARP for future device implementations and should not be used.

	Code	Address $[A_{15}-A_0]^{(1)}$	Data [DQ ₁₅ -DQ ₀]	Notes
Manufacturer Code	Manufacturer Code	0000H	00B0H	
Device Code	32M Top Parameter Device Code	0001H	00B4H	2
(32M-bit device)	32M Bottom Parameter Device Code	0001H	00B5H	3
Device Code	64M Top Parameter Device Code	0001H	00B0H	2
(64M-bit device)	64M Bottom Parameter Device Code	0001H	00B1H	3
Block Lock Configuration	Block is Unlocked		$DQ_0 = 0$	4
Code	Block is Locked	Block	$DQ_0 = 1$	4
	Block is not Locked-Down	Address + 2	$DQ_1 = 0$	4
	Block is Locked-Down		DQ ₁ = 1	4
Device Configuration Code	Read Configuration Register	0005H	RCRC	5
	Partition Configuration Register	0006H	PCRC	6
OTP	OTP Lock	0080H	OTP-LK	7
	OTP	0081-0088H	OTP	8

NOTES:

1. The address A_{20} - A_{16} to read the manufacturer, device, lock configuration, device configuration code and OTP data are shown in below table.

2. Top parameter device has its parameter blocks in the plane3 (The highest address).

3. Bottom parameter device has its parameter blocks in the plane0 (The lowest address)

4. DQ_{15} - DQ_{2} is reserved for future implementation.

5. RCRC=Read Configuration Register Code.

6. PCRC=Partition Configuration Register Code.

7. OTP-LK=OTP Block Lock configuration.

8. OTP=OTP Block data.

Table 7. Identifier Codes and OTP Address for Read Operation on Partition Configuration⁽¹⁾ for 32M-bit device

Partition	Configuration	Register	Address (32M-bit device)		
PCR.10	PCR.9	PCR.8	[A ₂₀ -A ₁₆]		
0	0	0	00H		
0	0	1	00H or 08H		
0	1	0	00H or 10H		
1	0	0	00H or 18H		
0	1	1	00H or 08H or 10H		
1	1	0	00H or 10H or 18H		
1	0	1	00H or 08H or 18H		
1	1	1	00H or 08H or 10H or 18H		

NOTES:

1. The address to read the identifier codes or OTP data is dependent on the partition which is selected when writing the Read Identifier Codes/OTP command (90H).

Table 8. Identifier Codes and OTP Address for Read Operation on Partition Configuration⁽¹⁾ for 64M-bit device

Partition	Configuration	Register	Address (64M-bit device)
PCR.10	PCR.9	PCR.8	[A ₂₁ -A ₁₆]
0	0	0	00H
0	0	1	00H or 10H
0	1	0	00H or 20H
1	0	0	00H or 30H
0	1	1	00H or 10H or 20H
1	1	0	00H or 20H or 30H
1	0	1	00H or 10H or 30H
1	1	1	00H or 10H or 20H or 30H

NOTES:

1. The address to read the identifier codes or OTP data is dependent on the partition which is selected when writing the Read Identifier Codes/OTP command (90H).

4.3 Read Query Command

The read query mode is initiated by writing the Read Query command (98H) to the target partition. Read operations to that partition output the query code (Common Flash Interface code) shown in Section 6. To terminate the operation, write another valid command to the partition. Once the internal WSM has started block erase, full chip erase, (page buffer) program or OTP program in one partition, the partition will not recognize the Read Query command until the WSM completes its operation or unless the WSM is suspended via the Block Erase Suspend or (Page Buffer) Program Suspend command. However, the Read Query command can be accepted in other partitions except for full chip erase or OTP program operation. Like the Read Array command, the Read Query command functions independently of the V_{PP} voltage and RST# must be at V_{IH}. Refer to Section 6 for more information about query code.

Asynchronous page mode and synchronous burst mode are not available for reading query code. Read operations for query code support single asynchronous read cycle or single synchronous read cycle.

4.4 Read Status Register Command

The status register may be read to determine when block erase, full chip erase, (page buffer) program or OTP program has been completed and whether the operation has been successfully completed or not (see Table 9). The status register can be read at any time by writing the Read Status Register command (70H) to the target partition. Subsequent read operations to that partition output the status register data until another valid command is written. The status register contents are latched on the falling edge of OE# or CE# whichever occurs later. OE# or CE# must toggle to V_{IH} before further reads to update the status register latch. The Read Status Register command functions independently of the V_{PP} voltage and RST# must be at V_{IH}.

Asynchronous page mode and synchronous burst mode are not available for reading status register. Read operations for status register support single asynchronous read cycle or single synchronous read cycle.

During the dual work operation, the status register data is read from the partition which is executing block erase or (page buffer) program operation. The memory array data can be read from other partitions which are not executing block erase or (page buffer) program operation. The partition to be accessed is automatically identified according to the input address.

4.5 Clear Status Register Command

Status register bits SR.5, SR.4, SR.3 and SR.1 that have been set to "1"s by the WSM can only be cleared by writing the Clear Status Register command (50H). This command functions independently of the V_{PP} voltage. RST# must be at V_{IH}. To clear the status register, write the Clear Status Register command and an address within the target partition to the CUI.

Status register bits SR.5, SR.4, SR.3 and SR.1 indicate various error conditions occurring after writing commands (see Table 9). When erasing multiple blocks or programming several words in sequence, clear these bits before starting each operation. The status register bits indicate an error for during the sequence.

After executing the Clear Status Register command, the partition returns to read array mode. This command clears only the status register of the addressed partition. During block erase suspend or (page buffer) program suspend, the Clear Status Register command is invalid and the status register cannot be cleared.

If XSR.7 is "0", the command is not accepted and a next Page Buffer Program command (E8H) should be issued again to check if page buffer is available or not. XSR.15-8 and XSR.6-0 are reserved for future use and should be masked out when polling the extended status register.			

4.6 Block Erase Command

The two-cycle Block Erase command initiates one block erase at the addressed block within the target partition. Read operations to that partition output the status register data of its partition. At the first cycle, command (20H) and an address within the block to be erased is written to the CUI, and command (D0H) and the same address as the first cycle is written at the second cycle. Once the Block Erase command is successfully written, the WSM automatically starts erase and verification processes. The data in the selected block are erased (becomes FFFFH). The system CPU can detect the block erase completion by analyzing the output data of the status register bit SR.7. The partition including the block to be erased remains in read status register mode after the completion of the block erase operation until another command is written to the CUI. Figure 5.1 and Figure 5.2 show a flowchart of the block erase operation.

Check the status register bit SR.5 at the end of block erase. If a block erase error is detected, the status register should be cleared before system software attempts corrective actions. The partition remains in read status register mode until a new command is written to that partition.

This two-cycle command sequence ensures that block contents are not accidentally erased. An invalid Block Erase command sequence will result in status register bits SR.5 and SR.4 of the partition being set to "1" and the operation will be aborted.

For reliable block erase operation, apply the specified voltage on V_{CC} and $V_{PPH1/2}$ on V_{PP} In the absence of this voltage, block erase operations are not guaranteed. For example, attempting a block erase at $V_{PP} \leq V_{PPLK}$ causes SR.5 and SR.3 being set to "1". Also, successful block erase requires that the selected block is unlocked. When block erase is attempted to the locked block, bits SR.5 and SR.1 will be set to "1".

Block erase operation may occur in only one partition at a time. Other partitions must be in one of the read modes.

4.7 Full Chip Erase Command

The two-cycle Full Chip Erase command erases all of the unlocked blocks. Before writing this command, all of the partitions should be ready (WSM should not be occupied by any partition). At the first cycle, command (30H) is written to the CUI, and command (D0H) is written at the second cycle. After writing the command, the device

outputs the status register data when any address within the device is selected. The WSM automatically starts the erase operation for all unlocked blocks, skipping the locked blocks. The full chip erase operation cannot be suspended through the erase suspend command (described later). The system CPU can detect the full chip erase completion by analyzing the output data of the status register bit SR.7. All the partitions remain in the read status register mode after the completion of the full chip erase operation until another command is written to the CUI. Figure 6.1 and Figure 6.2 show a flowchart of the full chip erase operation.

The WSM aborts the operation upon encountering an error during the full chip erase operation and leaves the remaining blocks not erased. After the full chip erase operation, check the status register bit SR.5. When a full chip erase error is detected, SR5 of all partitions will be set to "1". The status registers for all partitions should be cleared before system software attempts corrective actions. After that, retry the Full Chip Erase command or erase block by block using the Block Erase command.

This two-cycle command sequence ensures that block contents are not accidentally erased. An invalid Full Chip Erase command sequence will result in status register bits SR.5 and SR.4 of all partitions being set to "1" and the operation will be aborted.

For reliable full chip erase operation, apply the specified voltage on V_{CC} and $V_{PPH1/2}$ on V_{PP} In the absence of this voltage, full chip erase operations are not guaranteed. For example, attempting a full chip erase at $V_{PP} \leq V_{PPLK}$ causes SR.5 and SR.3 being set to "1".

As previously mentioned, the Full Chip Erase command erases all blocks except for the locked blocks. Unlike the block erase, the status register bits SR.5 and SR.1 are not set to "1" even if the locked block is included. However, when all blocks are locked, the bits SR.5 and SR.1 are set to "1" and the operation will not be executed.

If an error is detected during the full chip erase operation, error bits for all status registers are set to "1". This requires that the Clear Status Register command be written to all partitions to clear the error bits.

Dual work operation is not available during the full chip erase mode. The memory array data cannot be read in this mode. To return to the read array mode, write the Read Array command (FFH) to the CUI after the completion of the full chip erase operation.

4.8 Program Command

A two-cycle command sequence written to the target partition initiates a word program operation. Read operations to the target partition to be programmed output the status register data until another valid command is written. At the first cycle, write command (standard 40H or alternate 10H) and an address of memory location to be programmed, followed by the second write that specifies the address and data. The WSM then takes over, controlling the internal word program algorithm. The system CPU can detect the word program completion by analyzing the output data of the status register bit SR.7. Figure 7.1 and Figure 7.2 show a program flowchart.

The internal WSM verify only detects errors for "1"s that are not successfully programmed to "0"s. Check the status register bit SR.4 at the end of word program. If a word program error is detected, the status register should be cleared before system software attempts corrective actions. The partition remains in read status register mode until it receives another command.

For reliable word program operation, apply the specified voltage on V_{CC} and $V_{PPH1/2}$ on V_{PP} In the absence of this voltage, word program operations are not guaranteed. For example, attempting a word program at $V_{PP} \leq V_{PPLK}$ causes SR.4 and SR.3 being set to "1". Also, successful word program requires for the selected block is unlocked. When word program is attempted to the locked block, bits SR.4 and SR.1 will be set to "1".

Word program operation may occur in only one partition at a time. Other partitions must be in one of the read modes.

4.9 Page Buffer Program Command

The LH28F320BX/LH28F640BX series has two planes of 16-word page buffer, which can perform fast sequential programming up to 32 words. The data are once loaded to the page buffer and programmed to the flash array when the confirm command (D0H) is written. See the flowchart in Figure 8.1 and Figure 8.2.

The page buffer program is executed by at least fourcycle or up to 19-cycle command sequence. First, write the Page Buffer Program setup command (E8H) and start address to the partition's CUI. At this point, read operations to the target partition to be programmed output the extended status register data (see Table 10). Check the extended status register data. If the extended status register bit XSR 7 is "0", no page buffer is available and Page Buffer Program setup command which has just been written is ignored. To retry, continue monitoring XSR.7 by writing Page Buffer Program setup (E8H) with program address until XSR.7 transitions to "1". When XSR.7 transitions to "1", the setup command written is valid. Then, at the second cycle, write the word count [N]-1 and start address if the number of words to be programmed is [N] in total. That is, when the number of [N] is 1 word, write (00H); if [N] is 16 words, write (0FH). The word count [N]-1 must be less than or equal to OFH. Attempting to write more than OFH for the word count causes the sequence error and the status register bits SR.5 and SR.4 are set to "1". After writing a word count [N]-1, read operations to the target partition to be programmed output the status register data. At the third cycle following the write of [N]-1, write the first data to be programmed and start address to the partition's CUI. Lower 4 bits (A₀-A₃) of the start address also correspond to the page buffer address and the data are stored in the page buffer. At the fourth and subsequent cycles, write additional data and address, depending on the count. All subsequent address must lie within the start address plus the count. After writing the Nth word data, write the confirm command (D0H) and an address within the target partition at the last cycle. This initiates the WSM to being transferring the data from the page buffer to the flash array. If a command other than the confirm command (D0H) is written, sequence error occurs and status register bits SR.5 and SR.4 of the partition are set to "1". When the data are transferred from the page buffer to the flash array, the status register bit SR.7 is set to "0". Then, the target partition is in the page buffer program busy mode.

For additional page buffer program, write another Page Buffer Program setup command (E8H) and check XSR.7. The Page Buffer Program command can be queued while WSM is busy as long as XSR.7 indicates "1", because LH28F320BX/LH28F640BX series has two buffers. If an error occurs while programming, the device will stop programming and flush next page buffer program command which has been previously queued. Status register bit SR.4 is set to "1". SR.4 should be cleared before writing next command.

If the Page Buffer Program command is attempted past an erase block boundary, the device will program the data to the flash array up to an erase block boundary and then stop programming. The status register bits SR.5 and SR.4 will be set to "1" (command sequence error). SR.5 and SR.4 should be cleared before writing next command.

For reliable page buffer program operation, apply the specified voltage on V_{CC} and $V_{PPH1/2}$ on V_{PP} In the absence of this voltage, page buffer program operations are not guaranteed. For example, attempting a page buffer program at $V_{PP} \leq V_{PPLK}$ causes SR.4 and SR.3 being set to "1". Also, successful page buffer program requires for the selected block is unlocked. When page buffer program is attempted to the locked block, bits SR.4 and SR.1 will be set to "1".

During page buffer program, dual work operation is available. The array data can be read from partitions not being programmed.

Page buffer program operation may occur in only one partition at a time. Other partitions must be in one of the read modes.

Figure 8.2. Automated Page Buffer Program Flowchart (Continued)

4.10 Block Erase Suspend Command and Block Erase Resume Command

The Block Erase Suspend command (B0H) allows block erase interruption to read or program data in the blocks other than that which is suspended. This command is valid for the block erase operation and the full chip erase operation can not be suspended.

Once the block erase process starts in a partition, writing the Block Erase Suspend command to the partition requests that the WSM suspends the block erase sequence at a predetermined point in the algorithm. Read operations to the target partition after writing the Block Erase Suspend command access the status register. Status register bits SR.7 and SR.6 indicate if the block erase operation has been suspended (both will be set to "1"). Specification t_{WHRH2} or t_{EHRH2} defines the block erase suspend latency.

When the Block Erase Suspend command is written after the completion of the block erase operation, the partition returns to read array mode. Therefore, the Read Status Register command (70H) must be written to the target partition after writing the Block Erase Suspend command. If the status register bits SR.7 and SR.6 are set to "1", block erase has been suspended.

At this point, a Read Array command can be written to read data from blocks other than that which is suspended. A (Page Buffer) Program command sequence can also be written during block erase suspend to program data in other blocks. Using the (Page Buffer) Program Suspend command (see Section 4.11), a program operation can also be suspended during a block erase suspend.

During a word program operation with block erase suspended, status register bit SR.7 will return to "0". However, SR.6 will remain "1" to indicate the block erase suspend status.

If the Page Buffer Program setup command (E8H) is written to the target partition during block erase suspend in which SR.7 and SR.6 are set to "1", read operations to the target partition to be programmed output the extended status register data. In read extended status register mode, bit XSR.7 is only valid, which indicates that the written command (E8H) is available, and other bits (from XSR.6 to XSR.0) are invalid (see Table 10). When writing the word count [N]-1 and start address at next command cycle, the target partition returns to read status register mode and the status register bits SR.7 and SR.6 are set to "1". After the Page Buffer Program confirm command (D0H) is written, the status register bit SR.7 will return to "0". However, SR.6 will remain "1" to indicate the block erase suspend status.

The only other valid commands while block erase is suspended are Read Identifier Codes/OTP, Read Query, Read Status Register, Set Block Lock Bit, Clear Block Lock Bit, Set Block Lock-down Bit, Set Read Configuration Register and Block Erase Resume command.

To resume the block erase operation, write the Block Erase Resume command (D0H) to the partition. Status Register bits SR.7 and SR.6 will be automatically cleared. After the Block Erase Resume command is written, the target partition automatically outputs the status register data when read. V_{PP} must remain at $V_{PPH1/2}$ (at the same level before block erase suspended) while block erase is suspended. RST# must remain at V_{IH} and WP# must also remain at V_{IL} or V_{IH} (at the same level before block erase suspended). Block erase cannot resume until (page buffer) program operation initiated during block erase suspend is completed. Figure 9 shows the block erase suspend and block erase resume flowchart.

If the interval time from a Block Erase Resume command to a subsequent Block Erase Suspend command is shorter than t_{ERES} and its sequence is repeated, the block erase operation may not be finished.

Write Block Erase Resume		Data=D0H Addr=Within Block to be Suspended	

Figure 9. Block Erase Suspend and Block Erase Resume Flowchart

4.11 (Page Buffer) Program Suspend Command and (Page Buffer) Program Resume Command

The (Page Buffer) Program Suspend command (BOH) allows word and page buffer program interruption to read data from locations other than that which is suspended.

Once the (page buffer) program process starts in a partition, writing the (Page Buffer) Program Suspend command to the partition requests that the WSM suspends the (page buffer) program sequence at a predetermined point in the algorithm. Read operations to the target partition after writing the (Page Buffer) Program Suspend command access the status register. Status register bits SR.7 and SR.2 indicate if the (page buffer) program operation has been suspended (both will be set to "1"). Specification t_{WHRH1} or t_{EHRH1} defines the (page buffer) program suspend latency.

When the (Page Buffer) Program Suspend command is written after the completion of the (page buffer) program operation, the partition returns to read array mode. Therefore, the Read Status Register command (70H) must be written to the target partition after writing the (Page Buffer) Program Suspend command. If the status register bits SR.7 and SR.2 are set to "1", (page buffer) program has been suspended.

At this point, a Read Array command can be written to read data from locations other than that which is suspended.

The only other valid commands while (page buffer) program is suspended are Read Identifier Codes/OTP, Read Query, Read Status Register, Set Read Configuration Register and (Page Buffer) Program Resume command.

To resume the (page buffer) program operation, write the (Page Buffer) Program Resume command (D0H) to the partition. Status Register bits SR.7 and SR.2 will be automatically cleared. After the (Page Buffer) Program Resume command is written, the target partition automatically outputs the status register data when read. V_{PP} must remain at $V_{PPH1/2}$ (at the same level before (page buffer) program suspended) while (page buffer) program is suspended. RST# must remain at V_{IH} and WP# must also remain at V_{IL} or V_{IH} (at the same level before (page buffer) program suspended). Figure 10 shows the (page buffer) program resume flowchart.

If the interval time from a (Page Buffer) Program Resume command to a subsequent (Page Buffer) Program Suspend command is short and its sequence is repeated, the (page buffer) program operation may not be finished.

After the (Page Buffer) Program Suspend command is written to the 1st partition to suspend the program operation while the 2nd partition is in block erase suspend mode, the (Page Buffer) Program Resume command should be written to the 1st partition first to resume the suspended (page buffer) program operation. After that, the Block Erase Resume command is written to the 2nd partition to resume the suspended block erase operation. If the Block Erase Resume command is written before the (Page Buffer) Program Resume command, the Block Erase Resume command is ignored and the partition to which the Block Erase Resume command is written is set to read array mode with block erase suspended.

4.12 Set Block Lock Bit Command

The LH28F320BX/LH28F640BX series is provided with a block lock bit for each parameter block and main block. The features of set block lock bit is as follows:

- Any block can be independently locked by setting its block lock bit.
- The time required for block locking is less than the minimum command cycle time (minimum time from the rising edge of CE# or WE# to write the command to the next rising edge of CE# or WE#).
- Block erase, full chip erase or (page buffer) program on a locked block cannot be executed (see Table 11 and Table 12).
- At power-up or device reset, all blocks default to locked state, regardless of the states before power-off or reset operation. (Lock bit is volatile.)

The Set Block Lock Bit command is a two-cycle command. At the first cycle, command (60H) and an address within the block to be locked is written to the target partition. At the second cycle, command (01H) and the same address as the first cycle is written. Read operations to the target partition output the status register

data until another valid command is written. After writing the second cycle command, the block lock bit is set within the minimum command cycle time and the corresponding block is locked. To check the lock status, write the Read Identifier Codes/OTP command (90H) and an address within the target block. Subsequent reads at Block Base Address +2 (see Table 6 through Table 8) will output the lock/unlock status of that block. The lock/unlock status is represented by the output pin DQ₀. If the output of DQ₀ is "1", the block lock bit is set correctly. Figure 11 shows set block lock bit flowchart.

The two-cycle command sequence ensures that block is not accidentally locked. An invalid Set Block Lock Bit command sequence will result in both status register bits SR.5 and SR.4 being set to "1" and the operation will not be executed.

The Set Block Lock Bit command is available when the power supply voltage is specified level, independent of the voltage on $V_{\rm PP}$

At power-up or device reset, since all blocks default to locked state, write the Clear Block Lock Bit command described later to clear block lock bit before a erase or program operation.

	Current State				– – – – – – – – – –
State	WP#	DQ1 ⁽²⁾	DQ ₀ ⁽²⁾	State Name	Erase/Program Allowed? ⁽³⁾
[000]	0	0	0	Unlocked	Yes
[001] ⁽⁴⁾	0	0	1	Locked	No
[011]	0	1	1	Locked-down	No
[100]	1	0	0	Unlocked	Yes
[101] ⁽⁴⁾	1	0	1	Locked	No
[110] ⁽⁵⁾	1	1	0	Lock-down Disable	Yes
[111]	1	1	1	Lock-down Disable	No

Table 11. Functions of Block Lock⁽¹⁾ and Block Lock-Down

NOTES:

1. OTP (One Time Program) block has the lock function which is different from those described above.

2. $DQ_0=1$: a block is locked; $DQ_0=0$: a block is unlocked.

 $DQ_1=1$: a block is locked-down; $DQ_1=0$: a block is not locked-down.

3. Erase and program are general terms, respectively, to express: block erase, full chip erase and (page buffer) program operations.

- 4. At power-up or device reset, all blocks default to locked state and are not locked-down, that is, [001] (WP#=0) or [101] (WP#=1), regardless of the states before power-off or reset operation.
- 5. When WP# is driven to V_{IL} in [110] state, the state changes to [011] and the blocks are automatically locked.

	Current State Result after			Result after L	ock Command Writte	n (Next State)

Figure 11. Set Block Lock Bit and Set Block Lock-down Bit Flowchart

4.13 Clear Block Lock Bit Command

A locked block can be unlocked by writing the Clear Block Lock Bit command. The features of clear block lock bit is as follows:

- Any block can be independently unlocked by clearing its block lock bit.
- The time required to be unlocked is less than the minimum command cycle time (minimum time from the rising edge of CE# or WE# to write the command to the next rising edge of CE# or WE#).
- Block erase, full chip erase or (page buffer) program on an unlocked block can be executed (see Table 11 and Table 12).

The Clear Block Lock Bit command is a two-cycle command. At the first cycle, command (60H) and an address within the block to be unlocked is written to the target partition. At the second cycle, command (D0H) and the same address as the first cycle is written. Read operations to the target partition output the status register data until another valid command is written. After writing the second cycle command, the block lock bit is cleared within the minimum command cycle time and the corresponding block is unlocked. To check the unlock status, write the Read Identifier Codes/OTP command (90H) and an address within the target block. Subsequent reads at Block Base Address +2 (see Table 6 through Table 8) will output the lock/unlock status of that block. The lock/unlock status is represented by the output pin DQ_0 . If the output of DQ_0 is "0", the block lock bit is cleared correctly. Figure 12 shows clear block lock bit flowchart.

The two-cycle command sequence ensures that block is not accidentally unlocked. An invalid Clear Block Lock Bit command sequence will result in both status register bits SR.5 and SR.4 being set to "1" and the operation will not be executed.

The Clear Block Lock Bit command is available when the power supply voltage is specified level, independent of the voltage on $V_{\rm PP}$

4.14 Set Block Lock-Down Bit Command

The block lock-down bit, when set, increases the security for data protection. The block lock-down bit has the following functions.

- Any block can be independently locked-down by setting its block lock-down bit.
- The time required to be locked-down is less than the minimum command cycle time (minimum time from the rising edge of CE# or WE# to write the command to the next rising edge of CE# or WE#).
- \bullet Locked-down block is automatically locked regardless of WP# at V_{IL} or $V_{IH}.$
- When WP# is V_{IL}, locked-down blocks are protected from lock status changes.
- When WP# is V_{IH} , the lock-down bits are disabled and locked-down blocks can be individually unlocked by software command. These blocks can then be re-locked and unlocked as desired while WP# remains V_{IH} . When WP# goes V_{IL} , blocks that were previously marked lock-down return to the lock-down state regardless of any changes made while WP# was V_{IH} (see Table 13).
- At power-up or device reset, all blocks are not lockeddown regardless of the states before power-off or reset operation.

(Lock-down bit is volatile.)

• Lock-down bit cannot be cleared by software, only by power-off or device reset.

The Set Block Lock-down Bit command is a two-cycle command. At the first cycle, command (60H) and an address within the block to be locked-down is written to the target partition. At the second cycle, command (2FH) and the same address as the first cycle is written. Read operations to the target partition output the status register data until another valid command is written. After writing the second cycle command, the block lock-down bit is set within the minimum command cycle time and the corresponding block is locked-down. To check the lockdown status, write the Read Identifier Codes/OTP command (90H) and an address within the target block. Subsequent reads at Block Base Address +2 (see Table 6 through Table 8) will output the lock/unlock status of that block. The lock-down status is represented by the output pin DQ_1 . If the output of DQ_1 is "1", the block lock-down bit is set correctly. Figure 11 shows set block lock-down bit flowchart.

Figure 1	2. Cle	ar Block	Lock Bit	Flowchart

Standby

The two-cycle command sequence ensures that block is not accidentally locked-down. An invalid Set Block Lock-down Bit command sequence will result in both status register bits SR.5 and SR.4 being set to "1" and the operation will not be executed.

The Set Block Lock-down Bit command is available when the power supply voltage is specified level, independent of the voltage on V_{PP}

At power-up or device reset, since no blocks are lockeddown, write the Set Block Lock-down Bit command as necessary.

While WP# is V_{IH} , the lock-down bits are disabled but not cleared. Once any block is locked-down, it cannot be cleared until power-off or device reset.

4.15 OTP Program Command

OTP program is executed by a two-cycle command sequence. At the first cycle, command (C0H) and an address within the OTP block (see Figure 4) is written, followed by the second write that specifies the address and data. After writing the command, the device outputs the status register data when any address within the device is selected. The WSM then takes over, controlling the internal OTP program algorithm. The system CPU can detect the OTP program completion by analyzing the output data of the status register bit SR.7. Figure 13.1 and Figure 13.2 show OTP program flowchart.

The address written at the command cycle must be the address within the OTP block (refer to Figure 4). Writing an address outside the OTP block will cause a OTP program error and the status register bit SR.4 is set to "1". Clear the status register before writing next command.

The internal WSM verify only detects errors for "1"s that are not successfully programmed to "0"s. Check the status register bit SR.4 at the end of OTP program. If a OTP program error is detected, the status register should be cleared before system software attempts corrective actions.

For reliable OTP program operation, apply the specified voltage on V_{CC} and V_{PPH1/2} on V_{PP} In the absence of this voltage, OTP program operations are not guaranteed. For example, attempting an OTP program at $V_{PP} \leq V_{PPLK}$ causes SR.4 and SR.3 being set to "1". OTP program operation on locked area causes SR.4 and SR.1 being set to "1" and the operation will not be executed.

OTP program cannot be suspended through the (Page Buffer) Program Suspend command (B0H). Even if the (Page Buffer) Program Suspend command is written during OTP program operation, the suspend command will be ignored.

If an error is detected during the OTP program operation, error bits for all status registers are set to "1". This requires that the Clear Status Register command be written to all partitions to clear the error bits.

Dual work operation is not available while the OTP program mode, and the memory array data cannot be read even if that operation has been completed. To return to the read array mode, write the Read Array command (FFH) to the partition's CUI after the completion of the OTP program operation.

FULL STATUS CHECK PROCEDURE Read Status Register Data

Bus Operation	Command	Comments				
Standby		Check SR.3 1=V _{PP} Error Detect				
Standby		Check SR.1 1=Device Protect Detect				
Standby		Check SR.4 1=OTP Program Error				
SR.4, SR.3 and SR.1 are only cleared by the Clear Status Register command in cases where multiple locations are programmed before full status is checked.						

If an error is detected, clear the status register before attempting retry or other error recovery.

Figure 13.2. Automated OTP Program Flowchart (Continued)

The Read Configuration Register (RCR) bits are set by writing the Set Read Configuration Register command to the device.

This operation is initiated by a two-cycle command sequence. The read configuration register can be configured by writing the command with the read configuration register code. At the first cycle, command (60H) and a read configuration register code is written. At the second cycle, command (03H) and the same address as the first cycle is written. The read configuration register code is placed on the address bus, A_{15} - A_0 , and is latched on the rising edge of ADV#, CE#, or WE# (whichever occurs first). The read configuration register code sets the device's read configuration, burst order, frequency configuration, and burst length. This command functions independently of the VPP voltage. RST# must be at V_{IH}. After executing this command, the partition returns to read array mode. The read configuration register bits RCR.13-11, RCR.9, RCR.8, RCR.7, RCR.6, RCR.3 and RCR.2-0 are only valid for synchronous burst mode. Figure 16 shows set read configuration register flowchart.

NOTES:

- The read configuration register code can be read via the Read Identifier Codes/OTP command (90H). Address 0005H on A_{15} A_0 contains the read configuration register code (see Table 6 through Table 8).
- All the bits in the read configuration register are set to "1" after device power-up or reset.
 - (Read configuration register bits are volatile.)

4.16.1 Device Read Configuration (Read Mode)

Each partition supports a high performance synchronous burst mode read configuration. The read configuration register bit RCR.15 sets the device read configuration (read mode; see Table 14).

All the parameter and main blocks support asynchronous read mode, asynchronous 8-word page mode and synchronous burst mode configuration.

Status register, query code, identifier codes, OTP block and configuration register codes can only be read in single asynchronous or single synchronous read mode.

••• Synchronous burst mode will be available for future device. Appendix to Spec No.: MFM2-J13207 Model No.: LRS1383 March 1, 2001

	1	0	1	5	≤ TBD MHz	≤ TBD MHz	

4.16.2 Frequency Configuration

The read configuration register bits RCR.13, RCR.12 and RCR.11 indicates the frequency configuration (see Table 14). The frequency configuration informs the number of clocks that must elapse after ADV# is driven active (V_{IL}) before data will be available. This value is determined by the input clock frequency. See Table 15 for the specific input CLK frequency configuration. Figure 14 shows data output latency from ADV# going V_{IL} for different frequency configuration codes.

4.16.3 Data Output Configuration

The data output configuration, shown by RCR.9 (see Table 14), determines the number of clocks that data will be held valid. The data hold time for the LH28F320BX/LH28F640BX series can be set to one clock or two clocks (see Figure 15).

••• Synchronous burst mode will be available for future device. Appendix to Spec No.: MFM2-J13207 Model No.: LRS1383 March 1, 2001

4.16.4 WAIT# Configuration

The WAIT# configuration bit RCR.8 (see Table 14) controls the WAIT# output signal. This output signal can be set to be asserted during or one CLK cycle before an output delay occurs, when the burst read crosses the first 64-word boundary in continuous burst length or the 4- or 8-word burst length with no-wrap mode. Its setting will depend on the system and CPU characteristic.

4.16.5 Burst Sequence

The burst sequence bit RCR.7 (see Table 14) determines the order in which data is addressed in synchronous burst mode. This order is configurable to either linear or Intel burst order. The continuous burst length only supports linear burst order. The order will be determined by the CPU characteristic. Refer to Table 16 for linear burst order and Intel burst order in detail.

4.16.6 Clock Configuration

The clock configuration bit RCR.6 (see Table 14) configures the device to start a burst cycle, output data, and assert WAIT# on the rising or falling edge of the clock. This CLK flexibility enables interfacing the LH28F320BX/LH28F640BX series Flash memory to a wide range of burst CPUs.

4.16.7 Burst Wrap

The burst wrap bit RCR.3 (see Table 14) determines the wrap mode as follows.

- 4- or 8-word burst-accesses are performed within the burst-length boundary in wrap mode (RCR.3="0").
- 4- or 8-word and continuous burst-accesses cross the burst-length boundaries in no-wrap mode (RCR.3="1").

No-wrap mode is only valid for linear burst order (RCR.7="1").

No-wrap mode (RCR.3="1") enables WAIT# to hold off the system processor, as it does in the continuous burst mode. In the no-wrap mode, the device operates similar to continuous linear burst mode but consumes less power during 4- and 8-word bursts. Refer to Table 16 for burst wrap in detail. For example, if RCR.3="0" (wrap mode) and RCR.2-0=001 (4-word burst length), then possible linear burst sequences are 0-1-2-3, 1-2-3-0, 2-3-0-1 and 3-0-1-2.

If RCR.3="1" (no-wrap mode) and RCR.2-0=001 (4-word burst length), then possible linear burst sequences are 0-1-2-3, 1-2-3-4, 2-3-4-5 and 3-4-5-6. No-wrap mode not only enables limited non-aligned sequential burst, but also reduces power by minimizing the number of internal read operations.

4.16.8 Burst Length

The burst length is the number of words that the device will output. The read configuration register bits RCR.2-0 (see Table 14) set the burst length. The LH28F320BX/LH28F640BX series supports burst lengths of four and eight words. It also supports a continuous burst mode. In continuous burst mode, the device will linearly output data until the internal burst counter reaches the end of the device's burst-able address space or a partition boundary. Refer to Table 16 for burst length in detail.

4.16.8.1 Continuous Burst Length

In continuous burst mode or 4-, 8-word burst with nowrap (RCR.3="1") mode, the flash memory may cause an output delay when the burst read crosses the first 64-word boundary. It depends on the starting address whether an output delay will occur or not. When the starting address is aligned to a 64-word boundary, the delay will not occur. If the starting address is the end of a 64-word boundary, the output delay will be equal to the frequency configuration setting; this is the worst case delay. The delay will only take place once during a continuous burst access. If the burst read never crosses a 64-word boundary, the delay will never happen. The WAIT# output pin is used in continuous burst mode or 4-, 8-word burst with no-wrap mode to inform the system if this output delay occurs.

4.17 Set Partition Configuration Register Command

The Partition Configuration Register (PCR) bits are set by writing the Set Partition Configuration Register command to the device.

This operation is initiated by a two-cycle command sequence. The partition configuration register can be configured by writing the command with the partition configuration register code. At the first cycle, command (60H) and a partition configuration register code is written. At the second cycle, command (04H) and the same address as the first cycle is written. The partition configuration register code is placed on the address bus, A₁₅ - A₀, and is latched on the rising edge of ADV#, CE#, or WE# (whichever occurs first). The partition configuration register code sets the partition boundaries. This command functions independently of the VPP voltage. RST# must be at VIH. After executing this command, the device returns to read array mode and status registers are cleared. Figure 16 shows set partition configuration register flowchart.

NOTES:

- The partition configuration register code can be read via the Read Identifier Codes/OTP command (90H). Address 0006H on A_{15} A_0 contains the partition configuration register code (see Table 6 through Table 8).
- Partition configuration after device power-up or reset is as follows.
- (Partition configuration register bits are volatile.) Plane 0-2 are merged into one partition. (top parameter device)
 - Plane1-3 are merged into one partition. (bottom parameter device)

4.17.1 Partition Configuration

The partition configuration shown in Table 17 determines the partiton boundaries for the dual work (simultaneous read while erase/program) operation. The partition boundaries can be set to any plane boundaries. If the partition configuration register bits PCR.10-8 (PC.2-0) are set to "001", the partition boundary is set between plane0 and plane1. There are two partitions in this configuration. Plane1-3 are merged to one partition. Status registers for plane1-3 are also merged to one. If the partition configuration register bits are set to "101", the partition boundaries are set between plane0 and plane1 and between plane2 and plane3. There are three partitions in this configuration. Plane1-2 are merged to one partition. If the partition configuration register bits are set to "111", there are four partitions. Each partition is just the same as each plane. Figure 17 illustrates the various partition configuration.

Rev. 2.20

5.1 Hardware Design Considerations

5.1.1 Control using RST#, CE# and OE#

The device will often be used in large memory arrays. SHARP provides three control input pins to accommodate multiple memory connection. Three control input pins, RST#, CE# and OE# provide for:

- Minimize the power consumption of the memory
- Avoid data confliction on the data bus

To effectively use these control input pins, access the desired memory by enabling the CE# through the address decoder. Connect OE# to READ# control signal of all memory devices and system. With these connections, the selected memory devices are activated and deselected memory devices are in standby mode. RST# should be connected to the system POWERGOOD signal to prevent unintended writes during system power transitions. POWERGOOD should toggle (once set to V_{IL}) during system reset.

5.1.2 Power Supply Decoupling

Flash memory's power switching characteristics require careful device decoupling for eliminating noises to the system power lines. System designers should consider standby current levels (I_{CCS}), active current levels (I_{CCR}) and transient peaks produced by falling and rising edges of CE# and OE#. Transient current magnitudes depend on the device outputs' capacitive and inductive loading. Two-line control and proper decoupling capacitor selection will suppress these transient voltage peaks. Each flash device should have a 0.1µF ceramic capacitor connected between each V_{CC} , V_{CCQ} and GND and between V_{PP} and GND (when V_{PP} is used as 12V supply). These high-frequency, inherently low-inductance capacitors should be placed as close as possible to the package leads. Additionally, for every eight devices, a 4.7µF electrolytic capacitor should be placed at the array's power supply connection between V_{CC} and GND. These capacitors will overcome voltage slumps caused by circuit board trace inductance.

5.1.3 V_{PP} Traces on Printed Circuit Boards

The V_{PP} pin on the LH28F320BX/LH28F640BX series Flash memory is only used to monitor the power supply voltage and is not used for a power supply pin except for 12V supply. Therefore, even when on-board writing to the flash memory on the system, it is not required to consider that V_{PP} supplies the currents on the printed circuit boards.

However, in erase or program operations with applying $12V\pm0.3V$ to V_{PP} pin, V_{PP} is used for the power supply pin. When executing these operations, V_{PP} trace widths and layout should be similar to that of V_{CC} to supply the flash memory cells current for erasing or programming. Adequate V_{PP} supply traces, and decoupling capacitors placed adjacent to the component, will decrease spikes and overshoots.

5.1.4 V_{CC}, V_{PP}, RST# Transitions

If V_{PP} is lower than V_{PPLK} , V_{CC} is lower than V_{LKO} , or RST# is not at VIH, block erase, full chip erase, (page buffer) program and OTP program operation are not guaranteed. When V_{PP} error is detected, the status register bits SR.5 or SR.4 (depending on the attempted operation) and SR.3 will be set to "1". If RST# transitions to VIL during the block erase, full chip erase, (page buffer) program or OTP program operation, the status register bit SR.7 will remain "0" until reset operation has been completed. Then, the attempted operation will be aborted and the device will enter reset mode after the completion of the reset sequence. If RST# is taken VII. during a block erase, full chip erase, (page buffer) program or OTP program operation, the memory contents at the aborted location are no longer valid. Therefore, the proper command must be written again. And also, if V_{CC} transitions to lower than VLKO during a block erase, full chip erase, (page buffer) program or OTP program operation, the attempted operation will be aborted and the memory contents at the aborted location are no longer valid. Write the proper command again after V_{CC} transitions above V_{LKO}.

5.1.5 Power-Up/Down Protection

The LH28F320BX/LH28F640BX series is designed to offer protection against accidental block erase, full chip erase, (page buffer) program, OTP program due to noises during power transitions. When the device power-up, holding V_{PP} and RST# to GND until V_{CC} has reached the specified level and in stable. For additional information, please refer to the AP-007-SW-E *RST*#, V_{PP} Electric Potential Switching Circuit. After power-up, the LH28F320BX/LH28F640BX series defaults to the mode described in Section 2.1.

System designers must guard against spurious writes when V_{CC} voltages are above V_{LKO} and V_{PP} voltages are above V_{PPLK} , by referring to Section 5.3 and the following design considerations. Since both CE# and WE# must be at V_{IL} for a command write, driving either signal to V_{IH} will inhibit writes to the device. The CUI architecture provides additional protection because alternation of memory contents can only occur after successful completion of the two-step command sequences.

The individual block locking scheme, which enables each block to be independently locked, unlocked or locked-down, prevents the accidental data alternation. The device is also disabled until RST# is brought to V_{IH} , regardless of the state of its control inputs. By holding the device in reset during power-up/down, invalid bus conditions can be masked, providing yet another level of memory protection.

5.1.6 Power Dissipation

When designing portable systems, designers must consider battery power consumption not only during device operation, but also for data retention during system idle time. The LH28F320BX/LH28F640BX series' nonvolatility increases usable battery life because data is retained when system power is removed.

5.1.7 Automatic Power Savings

Automatic Power Savings (APS) provides low-power operation during active mode. APS mode allows the flash memory to put itself into a low current state when not being accessed. After data is read from the memory array and addresses not switching, the device enters the APS mode where typical I_{CC} current is comparable to I_{CCS} . The flash memory stays in this static state with outputs valid until a new location is read. Standard addresses are changed. During dual work operation (one partition being erased or programmed, while other partitions are one of read modes), the device cannot enter the APS mode even if the input address remains unchanged.

5.1.8 Reset Operation

During power-up/down or transitions of power supply voltage, hold the RST# pin at V_{IL} to protect data against noises which are caused by invalid bus conditions and initialize the internal circuitry in flash memory. Bringing RST# to V_{IL} resets the internal WSM (Write State Machine) and sets the status register to 80H.

After return from reset, a time t_{PHQV} is required until outputs are valid, and a delay, t_{PHWL} and t_{PHEL} , is required before a write sequence can be initiated. After this wake-up interval, normal operation is restored.

5.2 Software Design Considerations

5.2.1 WSM (Write State Machine) Polling

The status register bit SR.7 provides a software method of detecting block erase, full chip erase, (page buffer) program and OTP program completion. After the Block Erase, Full Chip Erase, (Page Buffer) Program or OTP Program command is written to the CUI (Command User Interface), SR.7 goes to "0". It will return to "1" when the WSM (Write State Machine) has completed the internal algorithm.

The status register bit SR.7 is "1" state when the device is in the following mode.

- The device can accept the next command.
- Block erase is suspended and (page buffer) program operation is not executed.
- (Page buffer) program is suspended.
- Reset mode

5.2.2 Attention to Program Operation

Do not *re*-program "0" data for the bit in which "0" has been already programmed. This *re*-program operation may generate the bit which cannot be erased.

To change the data from "1" to "0", take the following steps.

- Program "0" for the bit in which you want to change the data from "1" to "0".
- Program "1" for the bit in which "0" has been already programmed.

(When "1" is programmed, erase/program operations are not executed onto the memory cell in flash memory.)

For example, changing the data from "10111101" to "10111100" requires "11111110" programmed.

5.3 Data Protection Method

Noises having a level exceeding the limit specified in the specification may be generated under specific operating conditions on some systems. Such noises, when induced onto WE# signal or power supply, may be interpreted as false commands and causes undesired memory updating. To protect the data stored in the flash memory against unwanted writing, systems operating with the flash memory should have the following write protect designs, as appropriate:

- The below describes data protection method.
- 1) Protection of data in each block
 - Any locked block by setting its block lock bit is protected against the data alternation. When WP# is V_{IL} , any locked-down block by setting its block lock-down bit is protected from lock status changes. By using this function, areas can be defined, for example, program area (locked blocks), and data area (unlocked blocks).
 - For detailed block locking scheme, refer to Sections 4.12 to 4.14.
- 2) Protection of data with V_{PP} control
 - When the level of V_{PP} is lower than V_{PPLK} (V_{PP} lockout voltage), write functions to all blocks including OTP block are disabled. All blocks are locked and the data in the blocks are completely protected.
- 3) Protection of data with RST#
 - Especially during power transitions such as power-up and power-down, the flash memory enters reset mode by bringing RST# to V_{IL} , which inhibits write operation to all blocks including OTP block.
 - For detailed description on RST# control, refer to Section 5.1.5.
- Protection against noises on WE# signal

To prevent the recognition of false commands as write commands, system designer should consider the method for reducing noises on WE# signal.

5.4 High Performance Read Mode

5.4.1 CPU Compatibility

LH28F320BX/LH28F640BX series supports two highperformance read modes for the parameter and main blocks:

- Asynchronous read mode in which 8-word page mode is available
- Synchronous burst mode

These two read modes provide much higher read accesses than was previously used.

The asynchronous read mode is suitable for non-clocked memory systems and is compatible with standard pagemode ROM. If the memory subsystem has access to an external processor referenced clock, the synchronous burst mode is available for increased read performance. The clock frequency for synchronous burst mode is described in specifications. If the system CPU or ASIC does not support page-mode or burst accesses, single asynchronous and synchronous read modes can be used.

It depends on the setting in the read configuration register which read mode is available. When the read configuration register bit RCR.15 is set to "1", the device is in asynchronous read mode. If the bit RCR.15 is set to "0", the device is in synchronous burst mode. Upon reset, the device defaults to asynchronous read mode and is put into read array mode.

5.4.2 Features of ADV# and CLK

ADV# and CLK pins are important for synchronous burst mode.

• ADV# can be derived from the processor's transaction start signal. If the processor does not have this type of signal, other standard CPU control signals can be used to control ADV#. ADV# must toggle to inform the flash memory to latch a new address.

If this signal is not used in asynchronous read mode, CE# must toggle to inform the flash memory of a new address.

• CLK can be derived from the processor's memory clock output. If the processor does not supply this control signal to the memory subsystem, the signal can be received from the clock signal generator through a clock buffer. This buffer minimizes clock load and skew.

5.4.3 Address Latch

The internal address latch latches the address for read and write operations. The address latch is controlled by ADV#. When ADV# is V_{IL}, the latch is open. The latch closes when ADV# is driven high or upon the first rising (or falling) edge of CLK while ADV# is VII. This stores the current address on the bus into the flash memory device and lets the address bus change without affecting the flash. This pin works the same in write operations; the address to be written to the CUI is latched on the rising ADV# edge. Since write operations are asynchronous mode, CLK is ignored and the address is not latched on the clock edge. In asynchronous read mode, the address latch does not need to be used but addresses must then stay stable during the entire read operation. If ADV# is not used, which is fixed V_{II}, in asynchronous mode, addresses are latched on the rising edge of CE# during reads and on the rising edge of CE# or WE# whichever goes high first during writes.

5.4.4 Using Asynchronous Page Mode

After initial power-up or reset mode, the device defaults to asynchronous read mode in which 8-word page mode is available. The asynchronous page mode is available for the parameter and main blocks, and is not supported from other locations within the device, such as the status register, identifier codes, OTP block and query codes. In asynchronous page mode, CLK is ignored and ADV# must be held V_{IL} throughout the page access. Holding ADV# V_{IL} allows new page mode accesses. The initial valid address will store 8 words of data in the internal page buffer. Each word is then output onto the data bus by toggling the address A2-0.

If the asynchronous page mode is only used, CLK and ADV# can be tied to GND. Holding CLK and ADV# GND will minimize the power consumed by these two pins and will simplify the interface, making it compatible with standard flash memory and industry standard page mode ROMs. With ADV# at V_{IL} , the addresses cannot be latched into the device. Therefore, addresses must stay valid throughout the entire read cycle until CE# goes to V_{IH} . Figure 18 shows a waveform for asynchronous page mode read timing with ADV# held low. Note that the address A2-0 must be toggled to output the page-mode data.

In asynchronous read mode, the output of WAIT# is fixed to $\ensuremath{V_{\text{OH}}}$

5.4.5 Using Synchronous Burst Mode

Synchronous burst mode provides a performance increase over asynchronous read mode. It supports effective zero wait-state performance up to the frequency described in specifications. The synchronous burst mode is available for the parameter and main blocks, and is not supported from other locations within the device, such as the status register, identifier codes, OTP block and query codes. It is not possible to do a synchronous burst read across the partition boundary. Figure 19 illustrates a waveform for synchronous burst mode read timing. The valid addresses are asserted, and then the device will output the first data after certain delay time. Subsequent data will be output every CLK cycle.

There are two different considerations for an external interface logic whether or not the processor supports synchronous burst mode at boot-up.

- Case 1, the processor does not support synchronous burst mode at boot-up, but rather boots up in asynchronous read mode. This is the initial mode of the flash memory, so no special design considerations need to be made. After booting up, the processor can configure the read configuration register for synchronous burst mode.
- Case 2, the processor does support synchronous burst mode at boot-up. After return from reset, the flash memory defaults to asynchronous read mode, which is inherently slower than synchronous burst mode. External interface logic will be needed to inform the processor of this, and to insert wait states to match the flash memory's timing with the processor's timing. This logic is only necessary until the processor has a chance to set the flash memory device to synchronous burst mode, at which time the external logic must be notified of this change. This can be accomplished via a write-able register within the system wait-state logic or via a general purpose I/O (GPIO) pin. The GPIO pin may operate as an input into the system logic.

5.4.6 Using WAIT# in Burst Mode

LH28F320BX/LH28F640BX series supports 4-word, 8word and continuous burst modes. In continuous burst mode or 4-, 8-word burst with no-wrap (RCR.3="1") mode, WAIT# informs the system CPU whether output data is valid or not (refer to Section 4.16.8.1).

- WAIT#="1": there is valid data on the bus.
- WAIT#="0": the data on the bus is invalid.

When the output delay is encountered, the WAIT# pin will be asserted at a logic "0". This signal should be fed into the systems wait-state control logic or directly to the CPU. The WAIT# output pin is gated by CE# and OE#. If either CE# or OE# go to V_{IH} , the WAIT# output buffer turns off. An internal pull-up resistor holds WAIT# at a logic "1" state. Figure 20 shows a waveform for an output delay timing with ADV# at a logic "0".

WAIT# can be configured for assertion during the delay or one data cycle before the delay by setting the read configuration register bit RCR.8.

5.4.7 Single Read Mode

The following data can only be read in single asynchronous read mode or single synchronous read mode.

- Status register
- Query code
- Manufacturer code
- Device code
- Block lock configuration code
- Read configuration register code
- Partition configuration register code
- OTP block

A waveform of read timing for single asynchronous read mode and single synchronous read mode are shown in Figure 21 and Figure 22, respectively.

Single asynchronous read mode is compatible with previous SHARP flash memory devices. CLK is ignored in this mode. The valid addresses are asserted, and then the device will output data after certain delay time, such as t_{AVQV} , t_{VLQV} , t_{ELQV} or t_{GLQV} . Addresses are latched on the rising edge of ADV#. If ADV# is held V_{IL} , addresses must stay valid throughout the entire read cycle until CE# goes to V_{IH} .

In single synchronous read mode, after the valid addresses are asserted, the corresponding data will be output on the rising or falling edge of CLK, which is determined by the read configuration register bit RCR.6. Addresses are lathed when ADV# is driven high or upon the rising or falling edge of CLK while ADV# is V_{IL} . 4-word, 8-word or continuous burst accesses is not available in this mode. Therefore, the external input addresses must be incremented every read cycle.

•••• Synchronous burst mode will be available for future device. Appendix to Spec No.: MFM2-J13207 Model No.: LRS1383 March 1, 2001

•••• Synchronous burst mode will be available for future device. Appendix to Spec No.: MFM2-J13207 Model No.: LRS1383 March 1, 2001

6 Common Flash Interface

This section defines the data structure of the Common Flash Interface (CFI) code, which is called query code. Query code can be read by writing the Read Query command (98H) to the target partition's CUI. System software should confirm this code to gain critical information such as block size, density, bit organization and electrical specifications. Once this code has been obtained, the software will understand which command sets should be used to enable erases, programs and other operations for the flash memory device. The query code is part of an overall specification for multiple command set and control interface descriptions called Common Flash Interface or CFI.

Common Flash Interface for the LH28F320BX/ LH28F640BX series is now under development. Query code is described in the next version of Appendix.
