CY7C1512V18
CY7C1514V18

72-Mbit QDR-II™ SRAM 2-Word Burst Architecture

Features

- **Separate Independent Read and Write Data Ports**
 - Supports concurrent transactions
- **250-MHz clock for high bandwidth**
- **2-Word Burst on all accesses**
- **Double Data Rate (DDR) interfaces on both Read and Write ports (data transferred at 500 MHz) @ 250 MHz**
- **Two input clocks (K and \bar{K}) for precise DDR timing**
 - SRAM uses rising edges only
- **Two input clocks for output data (C and \bar{C}) to minimize clock-skew and flight-time mismatches**
- **Echo clocks (CQ and \bar{CQ}) simplify data capture in high speed systems**
- **Single multiplexed address input bus latches address inputs for both Read and Write ports**
- **Separate Port Selects for depth expansion**
- **Synchronous internally self-timed writes**
- **Available in x8, x9, x18, and x36 configurations**
- **Full data coherency, providing most current data**
- **Core $V_{DD} = 1.8V (\pm 0.1V)$; I/O $V_{DDQ} = 1.4V$ to V_{DD}**
- **Available in 165-ball FBGA package (15 x 17 x 1.4 mm)**
- **Offered in lead-free and non-lead free packages**
- **Variable drive HSTL output buffers**
- **JTAG 1149.1 compatible test access port**
- **Delay Lock Loop (DLL) for accurate data placement**

Configurations

CY7C1510V18 – 8M x 8
 CY7C1525V18 – 8M x 9
 CY7C1512V18 – 4M x 18
 CY7C1514V18 – 2M x 36

Selection Guide

| | 250 MHz | 200 MHz | 167 MHz | Unit |
|-----------------------------|---------|---------|---------|------|
| Maximum Operating Frequency | 250 | 200 | 167 | MHz |
| Maximum Operating Current | 950 | 850 | 800 | mA |

Functional Description

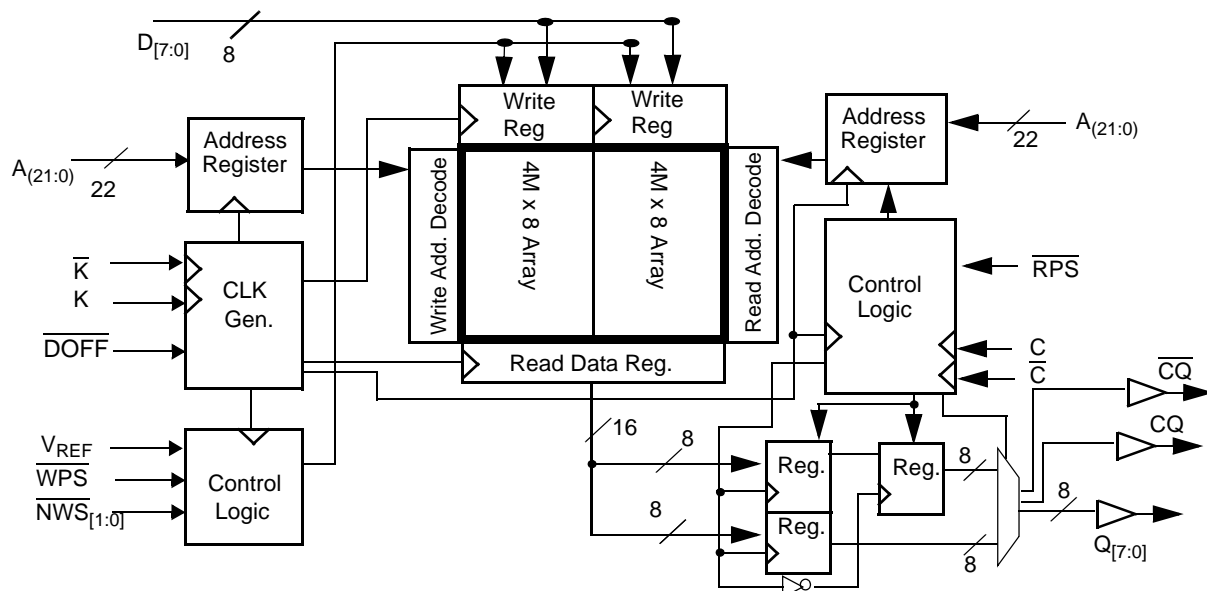

The CY7C1510V18, CY7C1525V18, CY7C1512V18, and CY7C1514V18 are 1.8V Synchronous Pipelined SRAMs, equipped with QDR-II architecture. QDR-II architecture consists of two separate ports to access the memory array. The Read port has dedicated Data Outputs to support Read operations and the Write Port has dedicated Data Inputs to support Write operations. QDR-II architecture has separate data inputs and data outputs to completely eliminate the need to "turn-around" the data bus required with common I/O devices. Access to each port is accomplished through a common address bus. The Read address is latched on the rising edge of the K clock and the Write address is latched on the rising edge of the \bar{K} clock. Accesses to the QDR-II Read and Write ports are completely independent of one another. In order to maximize data throughput, both Read and Write ports are equipped with Double Data Rate (DDR) interfaces. Each address location is associated with two 8-bit words (CY7C1510V18) or 9-bit words (CY7C1525V18) or 18-bit words (CY7C1512V18) or 36-bit words (CY7C1514V18) that burst sequentially into or out of the device. Since data can be transferred into and out of the device on every rising edge of both input clocks (K and \bar{K} and C and \bar{C}), memory bandwidth is maximized while simplifying system design by eliminating bus "turn-arounds."

Depth expansion is accomplished with Port Selects for each port. Port selects allow each port to operate independently.

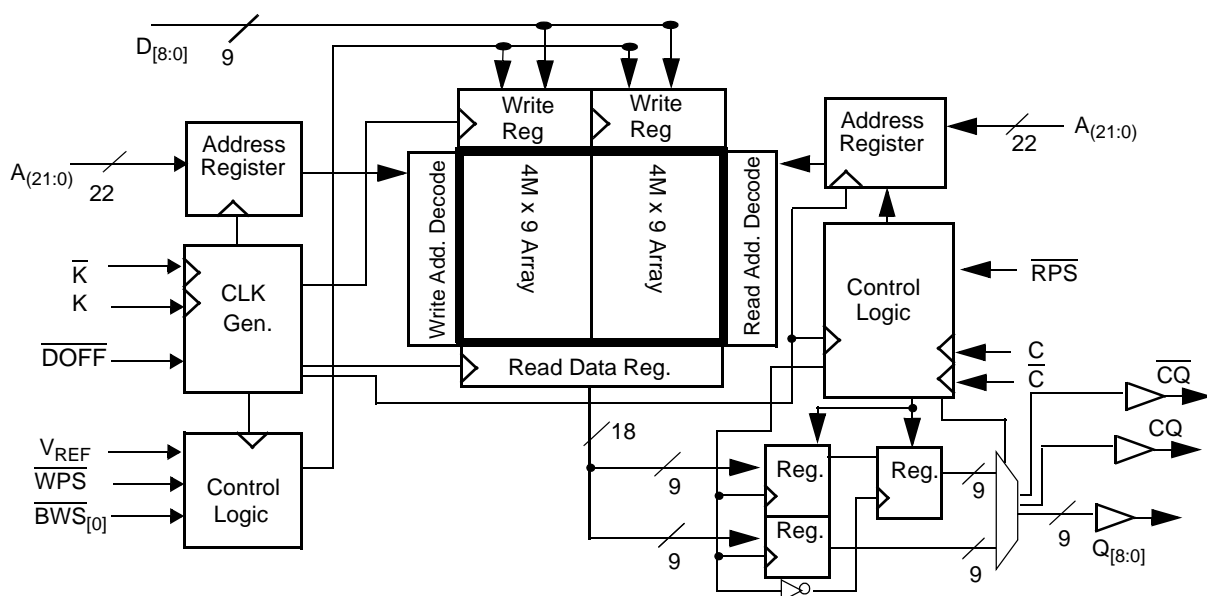

All synchronous inputs pass through input registers controlled by the K or \bar{K} input clocks. All data outputs pass through output registers controlled by the C or \bar{C} (or K or \bar{K} in a single clock domain) input clocks. Writes are conducted with on-chip synchronous self-timed write circuitry.

Pin Definitions

| Pin Name | I/O | Pin Description |
|--|---------------------|--|
| D _[x:0] | Input-Synchronous | Data input signals, sampled on the rising edge of K and \bar{K} clocks during valid write operations. CY7C1510V18 - D _[7:0] CY7C1525V18 - D _[8:0] CY7C1512V18 - D _[17:0] CY7C1514V18 - D _[35:0] |
| WPS | Input-Synchronous | Write Port Select, active LOW. Sampled on the rising edge of the K clock. When asserted active, a write operation is initiated. Deasserting will deselect the Write port. Deselecting the Write port will cause D _[x:0] to be ignored. |
| NWS ₀ , NWS ₁ | | Nibble Write Select 0,1 – active LOW. (CY7C1510V18 Only) Sampled on the rising edge of the K and \bar{K} clocks during write operations. Used to select which nibble is written into the device during the current portion of the write operations. Nibbles not written remain unaltered. NWS ₀ controls D _[3:0] and NWS ₁ controls D _[7:4] . All Nibble Write Selects are sampled on the same edge as the data. Deselecting a Nibble Write Select will cause the corresponding nibble of data to be ignored and not written into the device. |
| \overline{BWS}_0 , \overline{BWS}_1 , BWS ₂ , BWS ₃ | Input-Synchronous | Byte Write Select 0, 1, 2 and 3 – active LOW. Sampled on the rising edge of the K and \bar{K} clocks during write operations. Used to select which byte is written into the device during the current portion of the write operations. Bytes not written remain unaltered. CY7C1525V18 – \overline{BWS}_0 controls D _[8:0] , \overline{BWS}_1 controls D _[17:9] , CY7C1512V18 – \overline{BWS}_0 controls D _[8:0] , \overline{BWS}_1 controls D _[17:9] , CY7C1514V18 – \overline{BWS}_0 controls D _[8:0] , \overline{BWS}_1 controls D _[17:9] , BWS ₂ controls D _[26:18] and BWS ₃ controls D _[35:27] . All the Byte Write Selects are sampled on the same edge as the data. Deselecting a Byte Write Select will cause the corresponding byte of data to be ignored and not written into the device. |
| A | Input-Synchronous | Address Inputs. Sampled on the rising edge of the K (read address) and \bar{K} (write address) clocks during active read and write operations. These address inputs are multiplexed for both Read and Write operations. Internally, the device is organized as 8M x 8 (2 arrays each of 4M x 8) for CY7C1510V18, 8M x 9 (2 arrays each of 4M x 9) for CY7C1525V18, 4M x 18 (2 arrays each of 2M x 18) for CY7C1512V18 and 2M x 36 (2 arrays each of 1M x 36) for CY7C1514V18. Therefore, only 22 address inputs are needed to access the entire memory array of CY7C1510V18 and CY7C1525V18, 21 address inputs for CY7C1512V18 and 20 address inputs for CY7C1514V18. These inputs are ignored when the appropriate port is deselected. |
| Q _[x:0] | Outputs-Synchronous | Data Output signals. These pins drive out the requested data during a Read operation. Valid data is driven out on the rising edge of both the C and \bar{C} clocks during Read operations or K and \bar{K} when in single clock mode. When the Read port is deselected, Q _[x:0] are automatically tri-stated. CY7C1510V18 – Q _[7:0] CY7C1525V18 – Q _[8:0] CY7C1512V18 – Q _[17:0] CY7C1514V18 – Q _[35:0] |
| RPS | Input-Synchronous | Read Port Select, active LOW. Sampled on the rising edge of Positive Input Clock (K). When active, a Read operation is initiated. Deasserting will cause the Read port to be deselected. When deselected, the pending access is allowed to complete and the output drivers are automatically tri-stated following the next rising edge of the C clock. Each read access consists of a burst of two sequential transfers. |
| C | Input-Clock | Positive Input Clock for Output Data. C is used in conjunction with \bar{C} to clock out the Read data from the device. C and \bar{C} can be used together to deskew the flight times of various devices on the board back to the controller. See application example for further details. |
| \bar{C} | Input-Clock | Negative Input Clock for Output Data. \bar{C} is used in conjunction with C to clock out the Read data from the device. C and \bar{C} can be used together to deskew the flight times of various devices on the board back to the controller. See application example for further details. |

Pin Definitions (continued)

| Pin Name | I/O | Pin Description |
|-------------------|-----------------|---|
| K | Input-Clock | Positive Input Clock Input. The rising edge of K is used to capture synchronous inputs to the device and to drive out data through $Q_{[x:0]}$ when in single clock mode. All accesses are initiated on the rising edge of K. |
| \bar{K} | Input-Clock | Negative Input Clock Input. \bar{K} is used to capture synchronous inputs being presented to the device and to drive out data through $Q_{[x:0]}$ when in single clock mode. |
| CQ | Echo Clock | CQ is referenced with respect to C. This is a free running clock and is synchronized to the input clock for output data (C) of the QDR-II. In the single clock mode, CQ is generated with respect to K. The timings for the echo clocks are shown in the AC timing table. |
| \bar{CQ} | Echo Clock | \bar{CQ} is referenced with respect to \bar{C}. This is a free running clock and is synchronized to the input clock for output data (\bar{C}) of the QDR-II. In the single clock mode, \bar{CQ} is generated with respect to \bar{K} . The timings for the echo clocks are shown in the AC timing table. |
| ZQ | Input | Output Impedance Matching Input. This input is used to tune the device outputs to the system data bus impedance. CQ, \bar{CQ} and $Q_{[x:0]}$ output impedance are set to $0.2 \times RQ$, where RQ is a resistor connected between ZQ and ground. Alternately, this pin can be connected directly to V_{DDQ} , which enables the minimum impedance mode. This pin cannot be connected directly to GND or left unconnected. |
| \overline{DOFF} | Input | DLL Turn Off - Active LOW. Connecting this pin to ground will turn off the DLL inside the device. The timings in the DLL turned off operation will be different from those listed in this data sheet. |
| TDO | Output | TDO for JTAG. |
| TCK | Input | TCK pin for JTAG. |
| TDI | Input | TDI pin for JTAG. |
| TMS | Input | TMS pin for JTAG. |
| NC | N/A | Not connected to the die. Can be tied to any voltage level. |
| $V_{SS}/144M$ | Input | Address expansion for 144M. Can be tied to any voltage level. |
| $V_{SS}/288M$ | Input | Address expansion for 288M. Can be tied to any voltage level. |
| V_{REF} | Input-Reference | Reference Voltage Input. Static input used to set the reference level for HSTL inputs and Outputs as well as AC measurement points. |
| V_{DD} | Power Supply | Power supply inputs to the core of the device. |
| V_{SS} | Ground | Ground for the device. |
| V_{DDQ} | Power Supply | Power supply inputs for the outputs of the device. |

Functional Overview

The CY7C1510V18, CY7C1525V18, CY7C1512V18 and CY7C1514V18 are synchronous pipelined Burst SRAMs equipped with both a Read port and a Write port. The Read port is dedicated to Read operations and the Write port is dedicated to Write operations. Data flows into the SRAM through the Write port and out through the Read Port. These devices multiplex the address inputs in order to minimize the number of address pins required. By having separate Read and Write ports, the QDR-II completely eliminates the need to "turn-around" the data bus and avoids any possible data contention, thereby simplifying system design. Each access consists of two 8-bit data transfers in the case of CY7C1510V18, two 9-bit data transfers in the case of CY7C1525V18, two 18-bit data transfers in the case of CY7C1512V18 and two 36-bit data transfers in the case of CY7C1514V18, in one clock cycle.

Accesses for both ports are initiated on the rising edge of the positive Input Clock (K). All synchronous input timings are referenced from the rising edge of the input clocks (K and \bar{K}) and all output timings are referenced to the rising edge of output clocks (C and \bar{C} or K and \bar{K} when in single clock mode).

All synchronous data inputs ($D_{[x:0]}$) inputs pass through input registers controlled by the input clocks (K and \bar{K}). All synchronous data outputs ($Q_{[x:0]}$) outputs pass through output registers controlled by the rising edge of the output clocks (C and \bar{C} or K and \bar{K} when in single clock mode).

All synchronous control (RPS , WPS , $\bar{BWS}_{[x:0]}$) inputs pass through input registers controlled by the rising edge of the input clocks (K and \bar{K}).

CY7C1512V18 is described in the following sections. The same basic descriptions apply to CY7C1510V18, CY7C1525V18 and CY7C1514V18.

Read Operations

The CY7C1512V18 is organized internally as 2 arrays of 2Mx18. Accesses are completed in a burst of two sequential 18-bit data words. Read operations are initiated by asserting RPS active at the rising edge of the Positive Input Clock (K). The address is latched on the rising edge of the K Clock. The address presented to Address inputs is stored in the Read address register. Following the next K clock rise the corresponding lowest order 18-bit word of data is driven onto the $Q_{[17:0]}$ using \overline{C} as the output timing reference. On the subsequent rising edge of C, the next 18-bit data word is driven onto the $Q_{[17:0]}$. The requested data will be valid 0.45 ns from the rising edge of the output clock (C and \overline{C} or K and \overline{K} when in single clock mode).

Synchronous internal circuitry will automatically tri-state the outputs following the next rising edge of the Output Clocks (C/ \overline{C}). This will allow for a seamless transition between devices without the insertion of wait states in a depth expanded memory.

Write Operations

Write operations are initiated by asserting \overline{WPS} active at the rising edge of the Positive Input Clock (K). On the same K clock rise, the data presented to $D_{[17:0]}$ is latched and stored into the lower 18-bit Write Data register provided $BWS_{[1:0]}$ are both asserted active. On the subsequent rising edge of the Negative Input Clock (\overline{K}), the address is latched and the information presented to $D_{[17:0]}$ is stored into the Write Data Register provided $BWS_{[1:0]}$ are both asserted active. The 36 bits of data are then written into the memory array at the specified location. When deselected, the write port will ignore all inputs after the pending Write operations have been completed.

Byte Write Operations

Byte Write operations are supported by the CY7C1512V18. A write operation is initiated as described in the Write Operation section above. The bytes that are written are determined by BWS_0 and BWS_1 which are sampled with each 18-bit data word. Asserting the appropriate Byte Write Select input during the data portion of a write will allow the data being presented to be latched and written into the device. Deasserting the Byte Write Select input during the data portion of a write will allow the data stored in the device for that byte to remain unaltered. This feature can be used to simplify Read/Modify/Write operations to a Byte Write operation.

Single Clock Mode

The CY7C1512V18 can be used with a single clock that controls both the input and output registers. In this mode, the device will recognize only a single pair of input clocks (K and \overline{K}) that control both the input and output registers. This operation is identical to the operation if the device had zero skew between the K/\overline{K} and C/\overline{C} clocks. All timing parameters remain the same in this mode. To use this mode of operation, the user must tie C and \overline{C} HIGH at power-on. This function is a strap option and not alterable during device operation.

Concurrent Transactions

The Read and Write ports on the CY7C1512V18 operate completely independently of one another. Since each port latches the address inputs on different clock edges, the user can Read or Write to any location, regardless of the transaction on the other port. Also, reads and writes can be started in the same clock cycle. If the ports access the same location at the same time, the SRAM will deliver the most recent information associated with the specified address location. This includes forwarding data from a Write cycle that was initiated on the previous K clock rise.

Depth Expansion

The CY7C1512V18 has a Port Select input for each port. This allows for easy depth expansion. Both Port Selects are sampled on the rising edge of the Positive Input Clock only (K). Each port select input can deselect the specified port. Deselecting a port will not affect the other port. All pending transactions (Read and Write) will be completed prior to the device being deselected.

Programmable Impedance

An external resistor, RQ, must be connected between the ZQ pin on the SRAM and V_{SS} to allow the SRAM to adjust its output driver impedance. The value of RQ must be 5x the value of the intended line impedance driven by the SRAM. The allowable range of RQ to guarantee impedance matching with a tolerance of $\pm 15\%$ is between 175 Ω and 350 Ω , with $V_{DDQ} = 1.5V$. The output impedance is adjusted every 1024 cycles upon power-up to account for drifts in supply voltage and temperature.

Echo Clocks

Echo clocks are provided on the QDR-II to simplify data capture on high-speed systems. Two echo clocks are generated by the QDR-II. CQ is referenced with respect to C and \overline{CQ} is referenced with respect to \overline{C} . These are free-running clocks and are synchronized to the output clock (C/ \overline{C}) of the QDR-II. In the single clock mode, CQ is generated with respect to K and \overline{CQ} is generated with respect to \overline{K} . The timings for the echo clocks are shown in the AC Timing table.

DLL

These chips utilize a Delay Lock Loop (DLL) that is designed to function between 80 MHz and the specified maximum clock frequency. During power-up, when the \overline{DOFF} is tied HIGH, the DLL gets locked after 1024 cycles of stable clock. The DLL can also be reset by slowing or stopping the input clock K and \overline{K} for a minimum of 30 ns. However, it is not necessary for the DLL to be specifically reset in order to lock the DLL to the desired frequency. The DLL will automatically lock 1024 clock cycles after a stable clock is presented. The DLL may be disabled by applying ground to the \overline{DOFF} pin. For information refer to the application note "DLL Considerations in QDRII™/DDRII/QDRII+/DDRII+".

IEEE 1149.1 Serial Boundary Scan (JTAG)

These SRAMs incorporate a serial boundary scan test access port (TAP) in the FBGA package. This part is fully compliant with IEEE Standard #1149.1-1900. The TAP operates using JEDEC standard 1.8V I/O logic levels.

Disabling the JTAG Feature

It is possible to operate the SRAM without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW (V_{SS}) to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to V_{DD} through a pull-up resistor. TDO should be left unconnected. Upon power-up, the device will come up in a reset state which will not interfere with the operation of the device.

Test Access Port—Test Clock

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

Test Mode Select

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. It is allowable to leave this pin unconnected if the TAP is not used. The pin is pulled up internally, resulting in a logic HIGH level.

Test Data-In (TDI)

The TDI pin is used to serially input information into the registers and can be connected to the input of any of the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. For information on loading the instruction register, see the TAP Controller State Diagram. TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most significant bit (MSB) on any register.

Test Data-Out (TDO)

The TDO output pin is used to serially clock data-out from the registers. The output is active depending upon the current state of the TAP state machine (see Instruction codes). The output changes on the falling edge of TCK. TDO is connected to the least significant bit (LSB) of any register.

Performing a TAP Reset

A Reset is performed by forcing TMS HIGH (V_{DD}) for five rising edges of TCK. This RESET does not affect the operation of the SRAM and may be performed while the SRAM is operating. At power-up, the TAP is reset internally to ensure that TDO comes up in a high-Z state.

TAP Registers

Registers are connected between the TDI and TDO pins and allow data to be scanned into and out of the SRAM test circuitry. Only one register can be selected at a time through the instruction registers. Data is serially loaded into the TDI pin on the rising edge of TCK. Data is output on the TDO pin on the falling edge of TCK.

Instruction Register

Three-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the

TDI and TDO pins as shown in TAP Controller Block Diagram. Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.

When the TAP controller is in the Capture IR state, the two least significant bits are loaded with a binary "01" pattern to allow for fault isolation of the board level serial test path.

Bypass Register

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain chips. The bypass register is a single-bit register that can be placed between TDI and TDO pins. This allows data to be shifted through the SRAM with minimal delay. The bypass register is set LOW (V_{SS}) when the BYPASS instruction is executed.

Boundary Scan Register

The boundary scan register is connected to all of the input and output pins on the SRAM. Several no connect (NC) pins are also included in the scan register to reserve pins for higher density devices.

The boundary scan register is loaded with the contents of the RAM Input and Output ring when the TAP controller is in the Capture-DR state and is then placed between the TDI and TDO pins when the controller is moved to the Shift-DR state. The EXTEST, SAMPLE/PRELOAD and SAMPLE Z instructions can be used to capture the contents of the Input and Output ring.

The Boundary Scan Order tables show the order in which the bits are connected. Each bit corresponds to one of the bumps on the SRAM package. The MSB of the register is connected to TDI, and the LSB is connected to TDO.

Identification (ID) Register

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions table.

TAP Instruction Set

Eight different instructions are possible with the three-bit instruction register. All combinations are listed in the Instruction Code table. Three of these instructions are listed as RESERVED and should not be used. The other five instructions are described in detail below.

Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO. During this state, instructions are shifted through the instruction register through the TDI and TDO pins. To execute the instruction once it is shifted in, the TAP controller needs to be moved into the Update-IR state.

IDCODE

The IDCODE instruction causes a vendor-specific, 32-bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO pins and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state. The IDCODE instruction

is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

SAMPLE Z

The SAMPLE Z instruction causes the boundary scan register to be connected between the TDI and TDO pins when the TAP controller is in a Shift-DR state. The SAMPLE Z command puts the output bus into a High-Z state until the next command is given during the "Update IR" state.

SAMPLE/PRELOAD

SAMPLE/PRELOAD is a 1149.1 mandatory instruction. When the SAMPLE/PRELOAD instructions are loaded into the instruction register and the TAP controller is in the Capture-DR state, a snapshot of data on the inputs and output pins is captured in the boundary scan register.

The user must be aware that the TAP controller clock can only operate at a frequency up to 10 MHz, while the SRAM clock operates more than an order of magnitude faster. Because there is a large difference in the clock frequencies, it is possible that during the Capture-DR state, an input or output will undergo a transition. The TAP may then try to capture a signal while in transition (metastable state). This will not harm the device, but there is no guarantee as to the value that will be captured. Repeatable results may not be possible.

To guarantee that the boundary scan register will capture the correct value of a signal, the SRAM signal must be stabilized long enough to meet the TAP controller's capture set-up plus hold times (t_{CS} and t_{CH}). The SRAM clock input might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE/PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the CK and CK# captured in the boundary scan register.

Once the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO pins.

PRELOAD allows an initial data pattern to be placed at the latched parallel outputs of the boundary scan register cells prior to the selection of another boundary scan test operation.

The shifting of data for the SAMPLE and PRELOAD phases can occur concurrently when required—that is, while data captured is shifted out, the preloaded data can be shifted in.

BYPASS

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between the TDI and TDO pins. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

EXTEST

The EXTEST instruction enables the preloaded data to be driven out through the system output pins. This instruction also selects the boundary scan register to be connected for serial access between the TDI and TDO in the shift-DR controller state.

EXTEST OUTPUT BUS TRI-STATE

IEEE Standard 1149.1 mandates that the TAP controller be able to put the output bus into a tri-state mode.

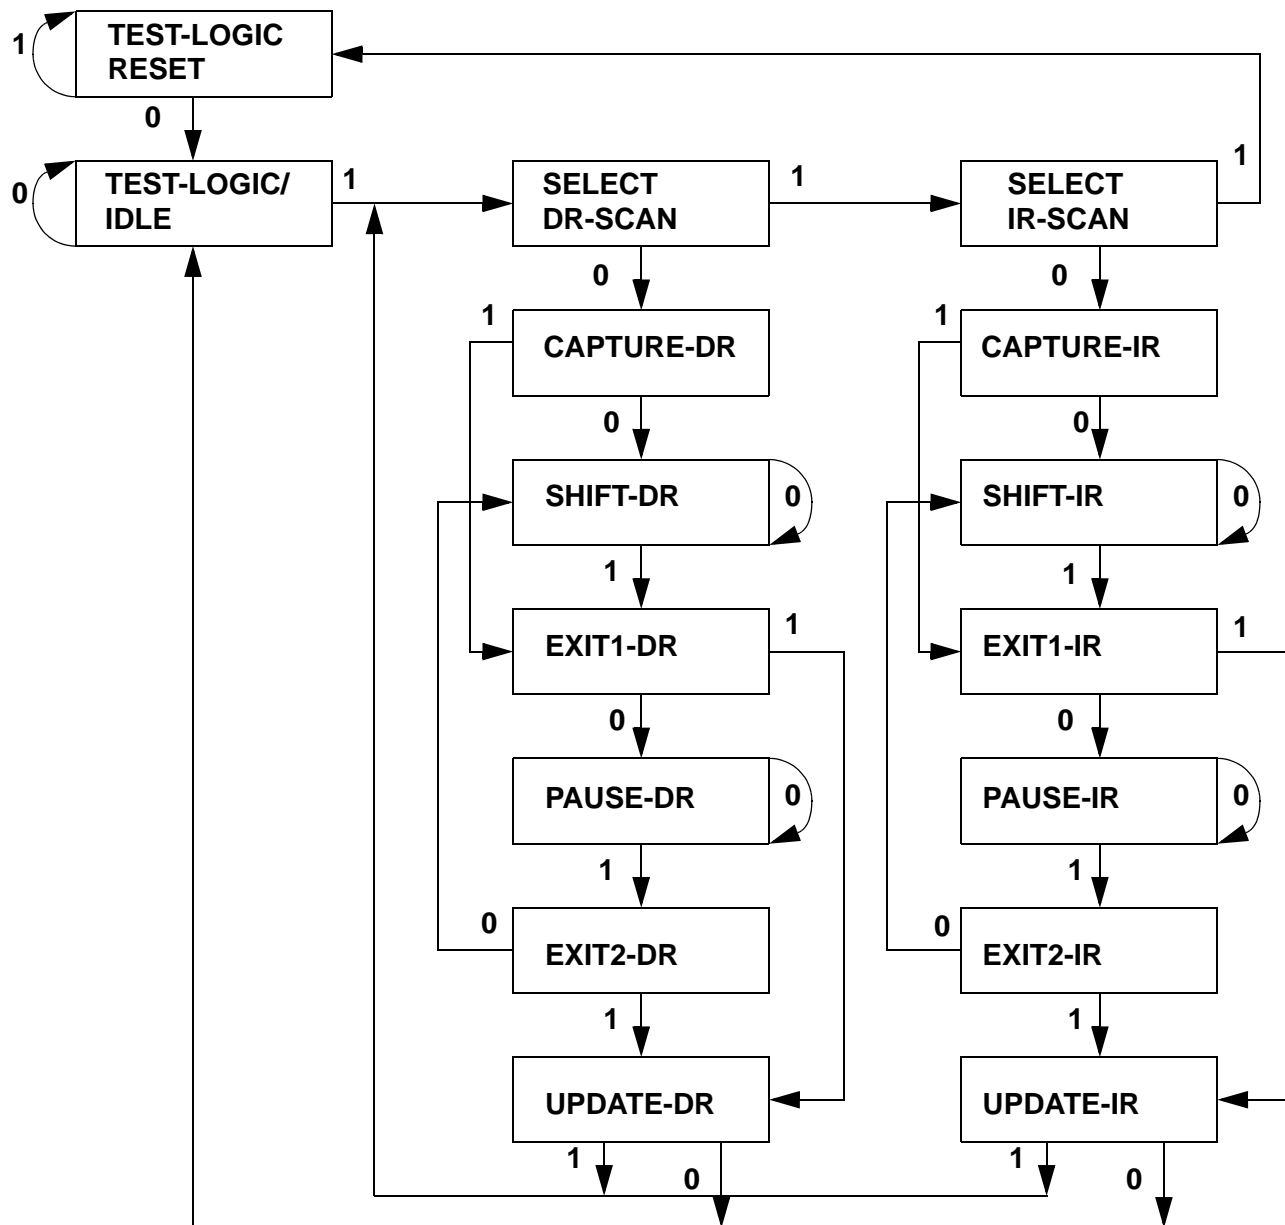

The boundary scan register has a special bit located at bit #108. When this scan cell, called the "extest output bus tri-state," is latched into the preload register during the "Update-DR" state in the TAP controller, it will directly control the state of the output (Q-bus) pins, when the EXTEST is entered as the current instruction. When HIGH, it will enable the output buffers to drive the output bus. When LOW, this bit will place the output bus into a High-Z condition.

This bit can be set by entering the SAMPLE/PRELOAD or EXTEST command, and then shifting the desired bit into that cell, during the "Shift-DR" state. During "Update-DR", the value loaded into that shift-register cell will latch into the preload register. When the EXTEST instruction is entered, this bit will directly control the output Q-bus pins. Note that this bit is pre-set LOW to enable the output when the device is powered-up, and also when the TAP controller is in the "Test-Logic-Reset" state.

Reserved

These instructions are not implemented but are reserved for future use. Do not use these instructions.

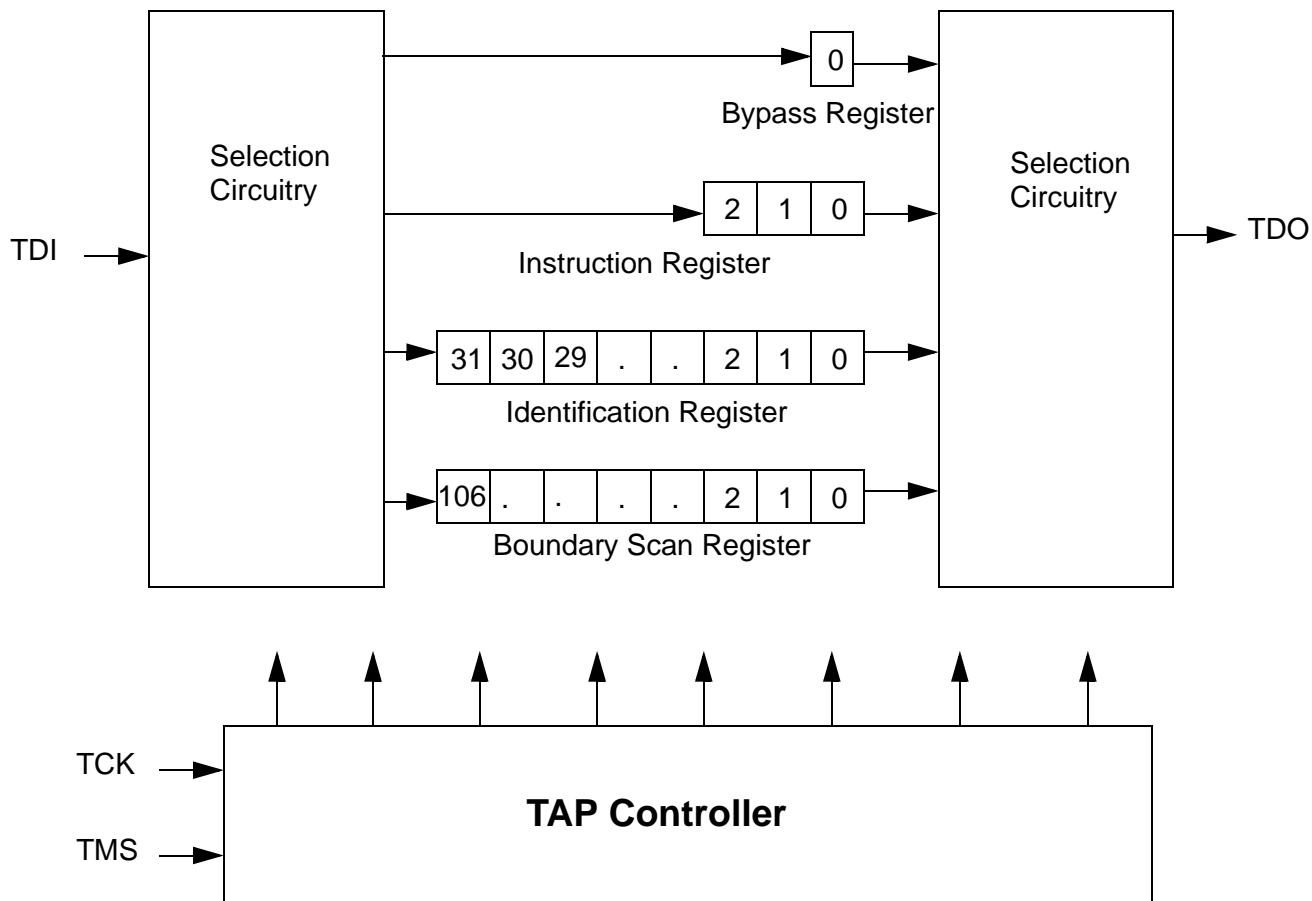

TAP Controller State Diagram^[10]

Note:

10. The 0/1 next to each state represents the value at TMS at the rising edge of TCK.

TAP Controller Block Diagram

TAP Electrical Characteristics Over the Operating Range^[16,19,11]

| Parameter | Description | Test Conditions | Min. | Max. | Unit |
|------------------|-------------------------------|--|---------------------|-----------------------|------|
| V _{OH1} | Output HIGH Voltage | I _{OH} = -2.0 mA | 1.4 | | V |

Power-Up Sequence in QDR-II SRAM^[14, 15]

QDR-II SRAMs must be powered up and initialized in a predefined manner to prevent undefined operations.

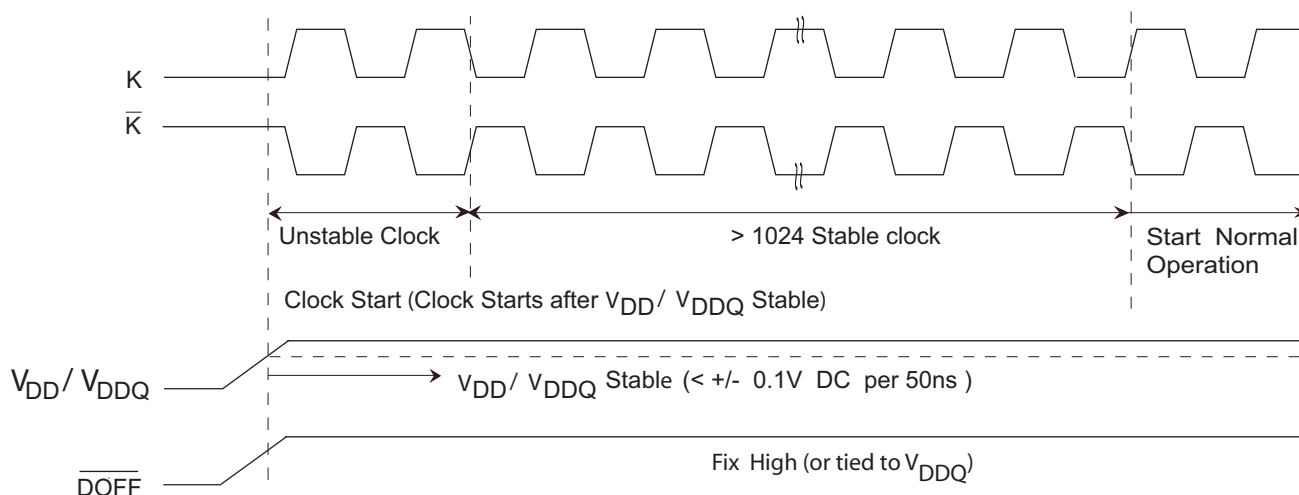

Power-Up Sequence

- Apply power and drive $\overline{\text{DOFF}}$ LOW (All other inputs can be HIGH or LOW)
 - Apply V_{DD} before V_{DDQ}
 - Apply V_{DDQ} before V_{REF} or at the same time as V_{REF}
- After the power and clock (K, \overline{K} , C, \overline{C}) are stable take $\overline{\text{DOFF}}$ HIGH
- The additional 1024 cycles of clocks are required for the DLL to lock.

DLL Constraints

- DLL uses either K or C clock as its synchronizing input. The input should have low phase jitter, which is specified as $t_{KC \text{ Var}}$
- The DLL will function at frequencies down to 80MHz.
- If the input clock is unstable and the DLL is enabled, then the DLL may lock to an incorrect frequency, causing unstable SRAM behavior.

Power-up Waveforms

Notes:

14. It is recommended that the $\overline{\text{DOFF}}$ pin be pulled HIGH via a pull up resistor of 1 Kohm.
15. During Power-Up, when the $\overline{\text{DOFF}}$ is tied HIGH, the DLL gets locked after 1024 cycles of stable clock.

Maximum Ratings

(Above which the useful life may be impaired.)

Storage Temperature -65°C to +150°C
 Ambient Temperature with
 Power Applied -55°C to +125°C
 Supply Voltage on V_{DD} Relative to GND -0.5V to +2.9V
 Supply Voltage on V_{DDQ} Relative to GND -0.5V to V_{DD}
 DC Voltage Applied to Outputs
 in High-Z State -0.5V to $V_{DDQ} + 0.5V$
 DC Input Voltage^[19] -0.5V to $V_{DD} + 0.5V$

Current into Outputs (LOW) 20 mA
 Static Discharge Voltage > 2001V
 (per MIL-STD-883, Method 3015)
 Latch-up Current > 200 mA

| V_{IL} | Input LOW Voltage ^[19, 13] | | -0.3 | | $V_{REF} - 0.1$ | V |
| I_X | Input Leakage Current | $GND \leq V_I \leq V_{DDQ}$ | -5 | | 5 | μA |
| I_{OZ} | Output Leakage Current | $GND \leq V_I \leq V_{DDQ}$, Output Disabled | -5 | | 5 | μA |
| V_{REF} ^[21] | Input Reference Voltage ^[15] | Typical Value = 0.75V | 0.68 | 0.75 | 0.95 | V |
| I_{DD} | V_{DD} Operating Supply | $V_{DD} = \text{Max.}, I_{OUT} = 0$ mA, $f = f_{MAX} = 1/t_{CYC}$ | 167 MHz | | 800 | mA |
| | | | 200 MHz | | 850 | mA |
| | | | 250 MHz | | 950 | mA |
| I_{SB1} | Automatic Power-down Current | Max. V_{DD} , Both Ports Deselected, $V_{IN} \geq V_{IH}$ or $V_{IN} \leq V_{IL}$, $f = f_{MAX} = 1/t_{CYC}$, Inputs Static | 167 MHz | | 360 | mA |
| | | | 200 MHz | | 380 | mA |
| | | | 250 MHz | | 400 | mA |

AC Input Requirements Over the Operating Range

| Parameter | Description | Test Conditions | Min. | Typ. | Max. | Unit |
|-----------|--------------------|-----------------|-----------------|------|-----------------|------|
| V_{IH} | Input HIGH Voltage | | $V_{REF} + 0.2$ | - | - | V |
| V_{IL} | Input LOW Voltage | | - | - | $V_{REF} - 0.2$ | V |

Capacitance^[22]

| Parameter | Description | Test Conditions | Max. | Unit |
|-----------|-------------------------|---|------|------|
| C_{IN} | Input Capacitance | $T_A = 25^\circ\text{C}$, $f = 1$ MHz, | 5.5 | pF |
| C_{CLK} | Clock Input Capacitance | $V_{DD} = 1.8V$ | 8.5 | pF |
| C_O | Output Capacitance | $V_{DDQ} = 1.5V$ | 8 | pF |

Notes:

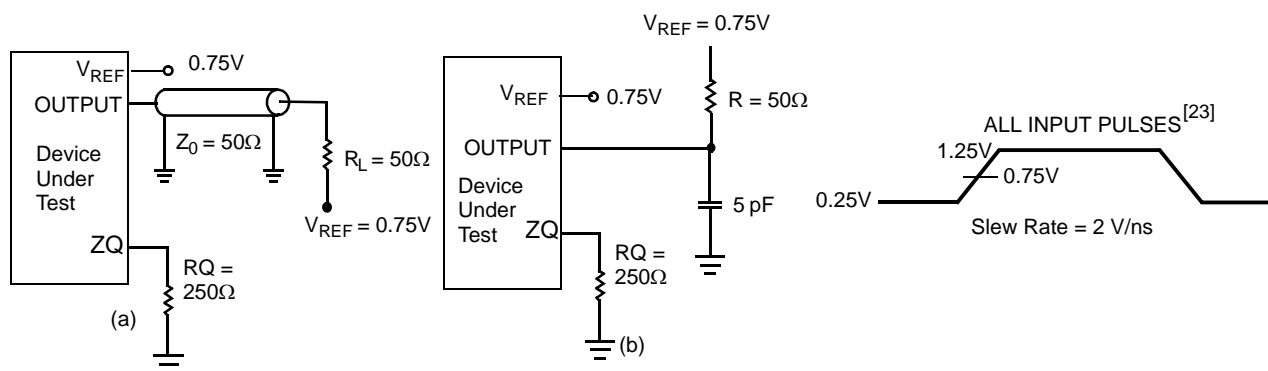

16. All voltage referenced to Ground.
17. Output are impedance controlled. $I_{OH} = -(V_{DDQ}/2)/(RQ/5)$ for values of 175 ohms $\leq RQ \leq$ 350 ohms.
18. Output are impedance controlled. $I_{OL} = (V_{DDQ}/2)/(RQ/5)$ for values of 175 ohms $\leq RQ \leq$ 350 ohms.
19. Overshoot: $V_{IH(AC)} < V_{DDQ} + 0.85V$ (Pulse width less than $t_{CYC}/2$), Undershoot: $V_{IL(AC)} > -1.5V$ (Pulse width less than $t_{CYC}/2$).
20. Power-up: Assumes a linear ramp from 0V to $V_{DD}(\text{min.})$ within 200 ms. During this time $V_{IH} < V_{DD}$ and $V_{DDQ} \leq V_{DD}$.
21. $V_{REF}(\text{min.}) = 0.68V$ or $0.46V_{DDQ}$, whichever is larger, $V_{REF}(\text{max.}) = 0.95V$ or $0.54V_{DDQ}$, whichever is smaller.
22. Tested initially and after any design or process change that may affect these parameters.

Thermal Resistance^[22]

| Parameter | Description | Test Conditions | FBGA | Unit |
|---------------|--|--|------|------|
| Θ_{JA} | Thermal Resistance (Junction to Ambient) | Test conditions follow standard test methods and procedures for measuring thermal impedance, per EIA/JESD51. | 16.2 | °C/W |
| Θ_{JC} | Thermal Resistance (Junction to Case) | | 2.3 | °C/W |

AC Test Loads and Waveforms

Note:

23. Unless otherwise noted, test conditions assume signal transition time of 2V/ns, timing reference levels of 0.75V, $V_{ref} = 0.75V$, $R_Q = 250\Omega$, $V_{DDQ} = 1.5V$, input pulse levels of 0.25V to 1.25V, and output loading of the specified I_{OL}/I_{OH} and load capacitance shown in (a) of AC test loads.

Switching Characteristics Over the Operating Range^[23, 24]

| Cypress Parameter | Consortium Parameter | Description | 250 MHz | | 200 MHz | | 167 MHz | | Unit |

| t _{KC Reset} | t _{KC Reset} | K Static to DLL Reset | 30 | – | 30 | – | 30 | – | ns |

Notes:

24. All devices can operate at clock frequencies as low as 119 MHz. When a part with a maximum frequency above 133 MHz is operating at a lower clock frequency, it requires the input timings of the frequency range in which it is being operated and will output data with the output timings of that frequency range.

25. This part has a voltage regulator internally; t_{POWER} is the time that the power needs to be supplied above V_{DD} minimum initially before a read or write operation can be initiated.

26. For D0 data signal on CY7C1525V18 device, t_{SD} is 0.5ns for 200MHz, and 250MHz frequencies.

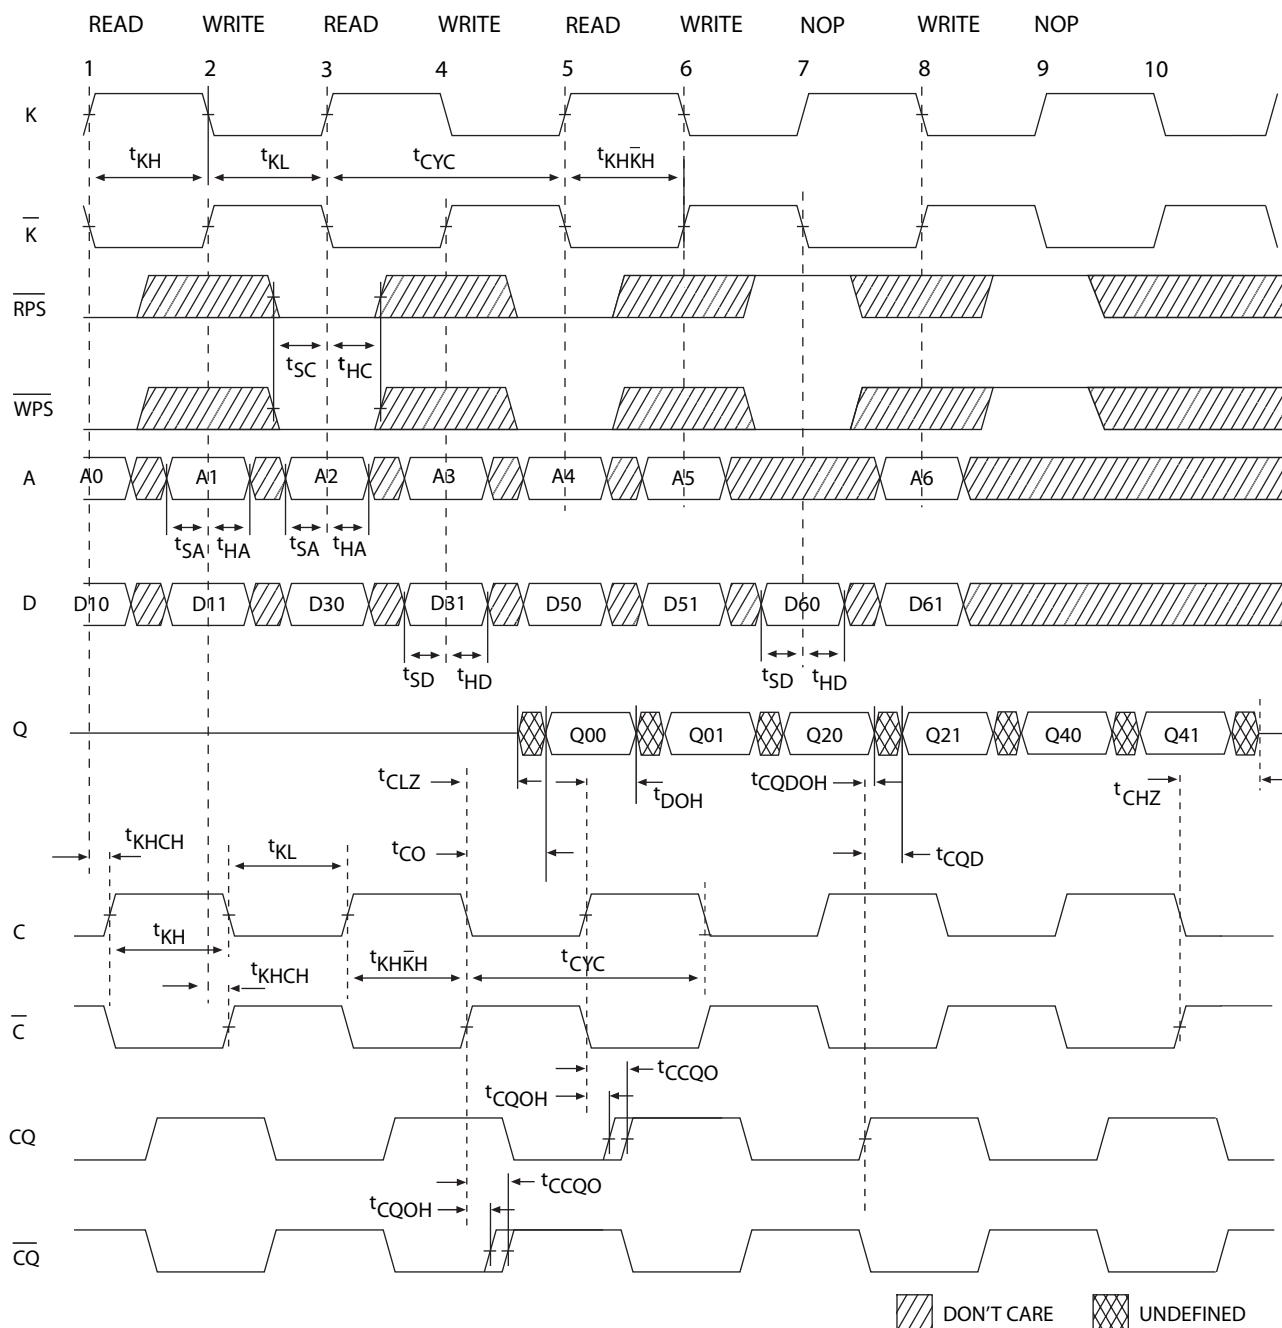

27. t_{CHZ}, t_{CLZ}, are specified with a load capacitance of 5 pF as in part (b) of AC Test Loads. Transition is measured ± 100 mV from steady-state voltage.

28. At any given voltage and temperature t_{CHZ} is less than t_{CLZ} and t_{CHZ} less than t_{CO}.

Switching Waveforms^[29, 30, 31]

Read/Write/Deselect Sequence

Notes:

29. Q00 refers to output from address A0. Q01 refers to output from the next internal burst address following A0, i.e. A0+1.

30. Output are disabled (High-Z) one clock cycle after a NOP.

31. In this example, if address A2 = A1, then data Q20 = D10 and Q21 = D11. Write data is forwarded immediately as read results. This note applies to the whole diagram

Ordering Information

Not all of the speed, package and temperature ranges are available. Please contact your local sales representative or visit www.cypress.com for actual products offered.

| Document Title: CY7C1510V18/CY7C1525V18/CY7C1512V18/CY7C1514V18 72-Mbit QDR™-II SRAM 2-Word Burst Architecture Document Number: 38-05489 | | | | |
|---|---------|------------|-----------------|---|
| REV. | ECN No. | Issue Date | Orig. of Change | Description of Change |
| ** | 201260 | See ECN | NJY | New Data Sheet |
| *A | 257089 | See ECN | NJY | Removed foot note 13 on page 12 Modified JTAG ID register definition table on page 21 Changed Max. value of t_{CYC} @ 250 MHz from 5.25 ns to 6.3 ns and Max. value of t_{CYC} @ 200 MHz from 6.3 ns to 7.9 ns. Changed Max. value of t_{KHCH} @ 200 MHz from 2.3 ns to 2.2 ns and Max. value of t_{KHCH} @ 167 MHz from 2.8 ns to 2.7 ns Included thermal values Modified capacitance values table: included capacitance values for x8, x18 and x36 options |
| *B | 319496 | See ECN | SYT | Removed CY7C1525V18 from the title Included 300-MHz Speed bin Added footnote #1 and accordingly edited the $V_{SS}/144M$ And $V_{SS}/288M$ on the Pin Definitions table. Added Industrial Temperature Grade Replaced TBDs for I_{DD} and I_{SB1} for 300 MHz, 250 MHz, 200 MHz and 167 MHz speed grades Changed the C_{IN} from 5 pF to 5.5 pF and C_O from 7 pF to 8 pF in the Capacitance Table Removed the capacitance value column for the x9 option from Capacitance Table Changed typo of bit # 47 to bit # 108 under the EXTEST OUTPUT BUS TRI-STATE on Page 18 Added lead-free product information Updated the Ordering Information by Shading and Unshading MPNs as per availability |
| *C | 403231 | See ECN | NXR | Converted from Preliminary to Final Added CY7C1525V18 to the title Removed 300-MHz Speed bin Changed address of Cypress Semiconductor Corporation on Page# 1 from "3901 North First Street" to "198 Champion Court" Changed C/C Pin Description in the features section and Pin Description Added power-up sequence details and waveforms Added foot notes # 14, 15, 16 on page# 19 Replaced Three-state with Tri-state Changed the description of I_X from Input Load Current to Input Leakage Current on page# 20 Modified the I_{DD} and I_{SB} current values Modified test condition in Footnote # 21 on page# 20 from $V_{DDQ} < V_{DD}$ to $V_{DDQ} \leq V_{DD}$ Replaced Package Name column with Package Diagram in the Ordering Information table Updated the Ordering Information |
| *D | 467290 | See ECN | NXR | Modified the ZQ Definition from Alternately, this pin can be connected directly to V_{DD} to Alternately, this pin can be connected directly to V_{DDQ} Included Maximum Ratings for Supply Voltage on V_{DDQ} Relative to GND Changed the Maximum Ratings for DC Input Voltage from V_{DDQ} to V_{DD} Changed t_{TCYC} from 100 ns to 50 ns, changed t_{TF} from 10 MHz to 20 MHz, changed t_{TH} and t_{TL} from 40 ns to 20 ns, changed t_{TMSS} , t_{TDS} , t_{CS} , t_{TMSH} , t_{TDIH} , t_{CH} from 10 ns to 5 ns and changed t_{TDOV} from 20 ns to 10 ns in TAP AC Switching Characteristics table Modified Power-Up waveform Added additional notes in the AC parameter section Changed the t_{SC} and t_{HC} value from 0.5 ns to 0.35 ns for 250 MHz , from 0.6 ns to 0.4 ns for 200 MHz, and from 0.7 ns to 0.5 ns for 167 MHz. Modified AC Switching Waveform Corrected the typo In the AC Switching Characteristics Table. Updated the Ordering Information Table |
