

# M24128 M24C64 M24C32

## 128 Kbit, 64 Kbit and 32 Kbit serial I<sup>2</sup>C bus EEPROM

### Features

- Two-wire I<sup>2</sup>C serial interface supports 400 kHz protocol
- Single supply voltages (see [Table 1](#) for root part numbers):
  - 2.5 V to 5.5 V
  - 1.8 V to 5.5 V
  - 1.7 V to 5.5 V
- Write Control input
- Byte and Page Write
- Random and Sequential Read modes
- Self-timed programming cycle
- Automatic address incrementing
- Enhanced ESD/latch-up protection
- More than 1 Million write cycles
- More than 40-year data retention
- Packages
  - ECOPACK® (RoHS compliant)

**Table 1. Device summary**

| Reference | Part number | Supply voltage |
|-----------|-------------|----------------|
| M24128    | M24128-BW   | 2.5 V to 5.5V  |
|           | M24128-BR   | 1.8 V to 5.5V  |
|           | M24128-BF   | 1.7 V to 5.5V  |
| M24C64    | M24C64-W    | 2.5 V to 5.5V  |
|           | M24C64-R    | 1.8 V to 5.5V  |
|           | M24C64-F    | 1.7 V to 5.5V  |
| M24C32    | M24C32-W    | 2.5 V to 5.5V  |
|           | M24C32-R    | 1.8 V to 5.5V  |
|           | M24C32-F    | 1.7 V to 5.5V  |

PDIP8 (BN)

SO8 (MN)  
150 mil width

TSSOP8 (DW)  
169 mil width

UFDFPN8 (MB)  
2 × 3 mm (MLP)

WLCSP (CS)

# 1 Description

The M24C32, M24C64 and M24128 devices are I<sup>2</sup>C-compatible electrically erasable programmable memories (EEPROM). They are organized as 4096 × 8 bits, 8192 × 8 bits and 16384 × 8 bits, respectively.

**Figure 1. Logic diagram**

I<sup>2</sup>C uses a two-wire serial interface, comprising a bi-directional data line and a clock line. The devices carry a built-in 4-bit Device Type Identifier code (1010) in accordance with the I<sup>2</sup>C bus definition.

The device behaves as a slave in the I<sup>2</sup>C protocol, with all memory operations synchronized by the serial clock. Read and Write operations are initiated by a Start condition, generated by the bus master. The Start condition is followed by a device select code and Read/Write bit ( $\overline{RW}$ ) (as described in [Table 3](#)), terminated by an acknowledge bit.

When writing data to the memory, the device inserts an acknowledge bit during the 9<sup>th</sup> bit time, following the bus master's 8-bit transmission. When data is read by the bus master, the bus master acknowledges the receipt of the data byte in the same way. Data transfers are terminated by a Stop condition after an Ack for Write, and after a NoAck for Read.

Table 2. Signal names

| Signal name     | Function       | Direction |
|-----------------|----------------|-----------|
| E0, E1, E2      | Chip Enable    | Input     |
| SDA             | Serial Data    | I/O       |
| SCL             | Serial Clock   | Input     |
| WC              | Write Control  | Input     |
| V <sub>CC</sub> | Supply voltage |           |
| V <sub>SS</sub> | Ground         |           |

Figure 2. DIP, SO, TSSOP and UDFPN connections

1. See [Package mechanical data](#) section for package dimensions, and how to identify pin-1.

Figure 3. M24128 WLCSP connections (top view, marking side, with balls on the underside)

## 2 Signal description

### 2.1 Serial Clock (SCL)

This input signal is used to strobe all data in and out of the device. In applications where this signal is used by slave devices to synchronize the bus to a slower clock, the bus master must have an open drain output, and a pull-up resistor must be connected from Serial Clock (SCL) to  $V_{CC}$ . (Figure 5 indicates how the value of the pull-up resistor can be calculated). In most applications, though, this method of synchronization is not employed, and so the pull-up resistor is not necessary, provided that the bus master has a push-pull (rather than open drain) output.

### 2.2 Serial Data (SDA)

This bi-directional signal is used to transfer data in or out of the device. It is an open drain output that may be wire-OR'ed with other open drain or open collector signals on the bus. A pull up resistor must be connected from Serial Data (SDA) to  $V_{CC}$ . (Figure 5 indicates how the value of the pull-up resistor can be calculated).

### 2.3 Chip Enable (E0, E1, E2)

These input signals are used to set the value that is to be looked for on the three least significant bits (b3, b2, b1) of the 7-bit device select code. These inputs must be tied to  $V_{CC}$  or  $V_{SS}$ , to establish the device select code as shown in Figure 4. When not connected (left floating), these inputs are read as low (0,0,0).

Figure 4. Device select code

### 2.4 Write Control ( $\overline{WC}$ )

This input signal is useful for protecting the entire contents of the memory from inadvertent write operations. Write operations are disabled to the entire memory array when Write Control ( $\overline{WC}$ ) is driven high. When unconnected, the signal is internally read as  $V_{IL}$ , and Write operations are allowed.

When Write Control ( $\overline{WC}$ ) is driven high, device select and Address bytes are acknowledged, Data bytes are not acknowledged.

### 3 Memory organization

The memory is organized as shown in [Figure 7](#).

**Figure 7. Block diagram**

## 4 Device operation

The device supports the I<sup>2</sup>C protocol. This is summarized in [Figure 6](#). Any device that sends data on to the bus is defined to be a transmitter, and any device that reads the data to be a receiver. The device that controls the data transfer is known as the bus master, and the other as the slave device. A data transfer can only be initiated by the bus master, which will also provide the serial clock for synchronization. The M24C32, M24C64 and M24128 devices are always slaves in all communications.

### 4.1 Start condition

Start is identified by a falling edge of Serial Data (SDA) while Serial Clock (SCL) is stable in the high state. A Start condition must precede any data transfer command. The device continuously monitors (except during a Write cycle) Serial Data (SDA) and Serial Clock (SCL) for a Start condition, and will not respond unless one is given.

### 4.2 Stop condition

Stop is identified by a rising edge of Serial Data (SDA) while Serial Clock (SCL) is stable and driven high. A Stop condition terminates communication between the device and the bus master. A Read command that is followed by NoAck can be followed by a Stop condition to force the device into the Standby mode. A Stop condition at the end of a Write command triggers the internal Write cycle.

### 4.3 Acknowledge bit (ACK)

The acknowledge bit is used to indicate a successful byte transfer. The bus transmitter, whether it be bus master or slave device, releases Serial Data (SDA) after sending eight bits of data. During the 9<sup>th</sup> clock pulse period, the receiver pulls Serial Data (SDA) low to acknowledge the receipt of the eight data bits.

### 4.4 Data Input

During data input, the device samples Serial Data (SDA) on the rising edge of Serial Clock (SCL). For correct device operation, Serial Data (SDA) must be stable during the rising edge of Serial Clock (SCL), and the Serial Data (SDA) signal must change *only* when Serial Clock (SCL) is driven low.

## 4.5 Memory addressing

To start communication between the bus master and the slave device, the bus master must initiate a Start condition. Following this, the bus master sends the device select code, shown in [Table 3](#) (on Serial Data (SDA), most significant bit first).

The device select code consists of a 4-bit device type identifier, and a 3-bit Chip Enable "Address" (E2, E1, E0). To address the memory array, the 4-bit device type identifier is 1010b.

Up to eight memory devices can be connected on a single I<sup>2</sup>C bus. Each one is given a unique 3-bit code on the Chip Enable (E0, E1, E2) inputs. When the device select code is received, the device only responds if the Chip Enable Address is the same as the value on the Chip Enable (E0, E1, E2) inputs.

The 8<sup>th</sup> bit is the Read/Write bit ( $\overline{RW}$ ). This bit is set to 1 for Read and 0 for Write operations.

If a match occurs on the device select code, the corresponding device gives an acknowledgment on Serial Data (SDA) during the 9<sup>th</sup> bit time. If the device does not match the device select code, it deselects itself from the bus, and goes into Standby mode.

**Table 6. Operating modes**

| Mode                 | $\overline{RW}$ bit | $\overline{WC}^{(1)}$ | Bytes                           | Initial sequence                                    |
|----------------------|---------------------|-----------------------|---------------------------------|-----------------------------------------------------|
| Current Address Read | 1                   | X                     | 1                               | Start, device select, $\overline{RW} = 1$           |
| Random Address Read  | 0                   | X                     | 1                               | Start, device select, $\overline{RW} = 0$ , Address |
|                      | 1                   | X                     |                                 | reStart, device select, $\overline{RW} = 1$         |
| Sequential Read      | 1                   | X                     | $\geq 1$                        | Similar to Current or Random Address Read           |
| Byte Write           | 0                   | $V_{IL}$              | 1                               | Start, device select, $\overline{RW} = 0$           |
| Page Write           | 0                   | $V_{IL}$              | $\leq 32$ for M24C64 and M24C32 | Start, device select, $\overline{RW} = 0$           |
|                      |                     |                       | $\leq 64$ for M24128            |                                                     |

1. X =  $V_{IH}$  or  $V_{IL}$ .

## 4.6 Write operations

Following a Start condition the bus master sends a device select code with the Read/Write bit (RW) reset to 0. The device acknowledges this, as shown in [Figure 9](#), and waits for two address bytes. The device responds to each address byte with an acknowledge bit, and then waits for the data Byte.

Writing to the memory may be inhibited if Write Control ( $\overline{WC}$ ) is driven high. Any Write instruction with Write Control ( $\overline{WC}$ ) driven high (during a period of time from the Start condition until the end of the two address bytes) will not modify the memory contents, and the accompanying data bytes are *not* acknowledged, as shown in [Figure 8](#).

Each data byte in the memory has a 16-bit (two byte wide) address. The Most Significant Byte ([Table 4](#)) is sent first, followed by the Least Significant Byte ([Table 5](#)). Bits b15 to b0 form the address of the byte in memory.

When the bus master generates a Stop condition immediately after the Ack bit (in the "10<sup>th</sup> bit" time slot), either at the end of a Byte Write or a Page Write, the internal Write cycle is triggered. A Stop condition at any other time slot does not trigger the internal Write cycle.

After the Stop condition, the delay  $t_{w\overline{}}$ , and the successful completion of a Write operation, the device's internal address counter is incremented automatically, to point to the next byte address after the last one that was modified.

During the internal Write cycle, Serial Data (SDA) is disabled internally, and the device does not respond to any requests.

## 4.7 Byte Write

After the device select code and the address bytes, the bus master sends one data byte. If the addressed location is Write-protected, by Write Control ( $\overline{WC}$ ) being driven high, the device replies with NoAck, and the location is not modified. If, instead, the addressed location is not Write-protected, the device replies with Ack. The bus master terminates the transfer by generating a Stop condition, as shown in [Figure 9](#).

## 4.8 Page Write

The Page Write mode allows up to 32 bytes (for the M24C32 and M24C64) or 64 bytes (for the M24128) to be written in a single Write cycle, provided that they are all located in the same 'row' in the memory: that is, the most significant memory address bits (b13-b6 for M24128, b12-b5 for M24C64, and b11-b5 for M24C32) are the same. If more bytes are sent than will fit up to the end of the row, a condition known as 'roll-over' occurs. This should be avoided, as data starts to become overwritten in an implementation dependent way.

The bus master sends from 1 to 32 bytes of data (for the M24C32 and M24C64) or 64 bytes of data (for the M24128), each of which is acknowledged by the device if Write Control ( $\overline{WC}$ ) is low. If Write Control ( $\overline{WC}$ ) is high, the contents of the addressed memory location are not modified, and each data byte is followed by a NoAck. After each byte is transferred, the internal byte address counter (inside the page) is incremented. The transfer is terminated by the bus master generating a Stop condition.

**Figure 9. Write mode sequences with  $\overline{WC} = 0$  (data write enabled)**

## 4.9 ECC (error correction code) and write cycling

The M24128 and M24C64 in UDFFPN8 (MLP)  $2 \times 3$  mm package and the M24128 in WLCSP package offer an ECC (error correction code) logic which compares each 4-byte word with its six associated EEPROM ECC bits. As a result, if a single bit out of 4 bytes of data happens to be erroneous during a read operation, the ECC detects it and replaces it by the correct value. The read reliability is therefore much improved by the use of this feature.

Note however that even if a single byte has to be written, 4 bytes are internally modified (plus the ECC word), that is, the addressed byte is cycled together with the three other bytes making up the word. It is therefore recommended to write by packets of 4 bytes in order to benefit from the larger amount of write cycles.

All M24C32, M24C64 and M24128 devices are qualified at 1 million (1 000 000) write cycles; the M24128 and M24C64 in UDFFPN8 (MLP)  $2 \times 3$  mm package and the M24128 in WLCSP package are qualified (at 1 million write cycles), using a cycling routine that writes to the device by multiples of 4-byte words.

Figure 10. Write cycle polling flowchart using ACK

## 4.10 Minimizing system delays by polling on ACK

During the internal Write cycle, the device disconnects itself from the bus, and writes a copy of the data from its internal latches to the memory cells. The maximum Write time ( $t_w$ ) is shown in [Table 17](#) and [Table 18](#), but the typical time is shorter. To make use of this, a polling sequence can be used by the bus master.

The sequence, as shown in [Figure 10](#), is:

1. Initial condition: a Write cycle is in progress.
2. Step 1: the bus master issues a Start condition followed by a device select code (the first byte of the new instruction).
3. Step 2: if the device is busy with the internal Write cycle, no Ack will be returned and the bus master goes back to Step 1. If the device has terminated the internal Write cycle, it responds with an Ack, indicating that the device is ready to receive the second part of the instruction (the first byte of this instruction having been sent during Step 1).

**Figure 11. Read mode sequences**

1. The seven most significant bits of the device select code of a Random Read (in the 1<sup>st</sup> and 4<sup>th</sup> bytes) must be identical.

## 4.11 Read operations

Read operations are performed independently of the state of the Write Control ( $\overline{WC}$ ) signal. After the successful completion of a Read operation, the device's internal address counter is incremented by one, to point to the next byte address.

## 4.12 Random Address Read

A dummy Write is first performed to load the address into this address counter (as shown in [Figure 11](#)) but *without* sending a Stop condition. Then, the bus master sends another Start condition, and repeats the device select code, with the Read/Write bit ( $\overline{RW}$ ) set to 1. The device acknowledges this, and outputs the contents of the addressed byte. The bus master must *not* acknowledge the byte, and terminates the transfer with a Stop condition.

## 4.13 Current Address Read

For the Current Address Read operation, following a Start condition, the bus master only sends a device select code with the Read/Write bit ( $\overline{RW}$ ) set to 1. The device acknowledges this, and outputs the byte addressed by the internal address counter. The counter is then incremented. The bus master terminates the transfer with a Stop condition, as shown in [Figure 11](#), *without* acknowledging the Byte.

## 4.14 Sequential Read

This operation can be used after a Current Address Read or a Random Address Read. The bus master *does* acknowledge the data byte output, and sends additional clock pulses so that the device continues to output the next byte in sequence. To terminate the stream of bytes, the bus master must *not* acknowledge the last byte, and *must* generate a Stop condition, as shown in [Figure 11](#).

The output data comes from consecutive addresses, with the internal address counter automatically incremented after each byte output. After the last memory address, the address counter 'rolls-over', and the device continues to output data from memory address 00h.

## 4.15 Acknowledge in Read mode

For all Read commands, the device waits, after each byte read, for an acknowledgment during the 9<sup>th</sup> bit time. If the bus master does not drive Serial Data (SDA) low during this time, the device terminates the data transfer and switches to its Standby mode.

## 7 DC and AC parameters

This section summarizes the operating and measurement conditions, and the DC and AC characteristics of the device. The parameters in the DC and AC characteristic tables that follow are derived from tests performed under the measurement conditions summarized in the relevant tables. Designers should check that the operating conditions in their circuit match the measurement conditions when relying on the quoted parameters.

**Table 8. Operating conditions (M24xxx-W)**

| Symbol   | Parameter                                      | Min. | Max. | Unit |

| $t_{DHDL}$                                                                       | $t_{BUF}$    | Time between Stop condition and next Start condition | 1300 |                  | ns   |
| $t_W$                                                                            |              | Write time                                           |      | 5 <sup>(5)</sup> | ms   |

1. Values recommended by the I<sup>2</sup>C-bus Fast-Mode specification.
2. To avoid spurious Start and Stop conditions, a minimum delay is placed between SCL=1 and the falling or rising edge of SDA.
3.  $t_{CLQV}$  is the time (from the falling edge of SCL) required by the SDA bus line to reach 0.8V<sub>CC</sub> in a compatible way with the I<sup>2</sup>C specification (which specifies  $t_{SU:DAT}(\text{min}) = 100 \text{ ns}$ ), assuming that the  $R_{bus} \times C_{bus}$  time constant is less than 500 ns (as specified in [Figure 5](#)).
4. For a reStart condition, or following a Write cycle.
5. For production lots assembled from 1st July 2007 (data code 727: week27, year 2007), the M24xxx-R (1.8 V to 5.5 V range) memories are specified with  $t_W = 5 \text{ ms}$  (instead of 10ms).

| $t_{CLQV}^{(2)(3)}$                                   | $t_{AA}$     | Clock low to next data valid (access time)           | 200  | 900        | ns   |
| $t_{CHDX}^{(4)}$                                      | $t_{SU:STA}$ | Start condition set up time                          | 600  |            | ns   |
| $t_{DLCL}$                                            | $t_{HD:STA}$ | Start condition hold time                            | 600  |            | ns   |
| $t_{CHDH}$                                            | $t_{SU:STO}$ | Stop condition set up time                           | 600  |            | ns   |
| $t_{DHDL}$                                            | $t_{BUF}$    | Time between Stop condition and next Start condition | 1300 |            | ns   |
| $t_W$                                                 |              | Write time                                           |      | $10^{(5)}$ | ms   |

1. Values recommended by the I<sup>2</sup>C-bus Fast-Mode specification.
2. To avoid spurious Start and Stop conditions, a minimum delay is placed between SCL=1 and the falling or rising edge of SDA.
3.  $t_{CLQV}$  is the time (from the falling edge of SCL) required by the SDA bus line to reach  $0.8V_{CC}$  in a compatible way with the I<sup>2</sup>C specification (which specifies  $t_{SU:DAT}(\min) = 100$  ns), assuming that the  $R_{bus} \times C_{bus}$  time constant is less than 500 ns (as specified in [Figure 5](#)).
4. For a reStart condition, or following a Write cycle.
5. For temperature range 6:  $t_{W(max)} = 5$  ms.  
For temperature range 5:  $t_{W(max)} = 10$  ms.

## 8 Package mechanical data

In order to meet environmental requirements, ST offers the M24C32, M24C64 and M24128 in ECOPACK® packages. These packages have a lead-free second level interconnect. The category of second level interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label. ECOPACK is an ST trademark. ECOPACK specifications are available at [www.st.com](http://www.st.com).

1. ST strongly recommends the use of the Automotive Grade devices for use in an automotive environment. The high reliability certified flow (HRCF) is described in the quality note QNEE9801. Please ask your nearest ST sales office for a copy.

2. Used only for device grade 3 and WLCSP packages.

For a list of available options (speed, package, etc.) or for further information on any aspect of this device, please contact your nearest ST sales office.
